Define the state vector $\mathbf{x}(t) = (E(t), D(t), I(t), F(t))^T$ representing energy reserves, cumulative damage, immune activation, and fatigue perception respectively, with activity intensity $u(t) \in [0, u_{\max}]$ as the control variable. The system dynamics follow from the models in Chapters 36–39:

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}, u) = \begin{pmatrix} J_{\text{production}}(\mathbf{x}) - J_{\text{demand}}(u) - E_{\text{repair}}(\mathbf{x}) \\ k_{\text{damage}} \cdot \text{ROS}(u, \mathbf{x}) - k_{\text{repair}} \cdot R(\mathbf{x}) \\ \sigma(\mathbf{x}, u) - \delta_I \cdot I \\ \alpha_F \cdot (D + \beta_F \cdot I) - \gamma_F \cdot F \end{pmatrix} \quad (41.3)$$

The patient seeks to maximize total functional capacity over a planning horizon $[0, T]$ while penalizing damage accumulation:

$$J[u] = \int_0^T \left[U(u(t)) - \lambda_D \cdot D(t) - \lambda_F \cdot F(t) \right] dt + \Phi(\mathbf{x}(T)) \quad (41.4)$$

where $U(u)$ is the utility of activity at intensity u , λ_D and λ_F are penalty weights for damage and fatigue, and $\Phi(\mathbf{x}(T))$ is a terminal cost penalizing unfavorable end-states. The Pontryagin maximum principle yields necessary conditions for the optimal activity schedule $u^*(t)$ through the Hamiltonian:

$$\mathcal{H}(\mathbf{x}, u, \lambda) = U(u) - \lambda_D D - \lambda_F F + \lambda^T \mathbf{f}(\mathbf{x}, u) \quad (41.5)$$

where the costate variables $\lambda(t)$ satisfy $\dot{\lambda} = -\partial \mathcal{H} / \partial \mathbf{x}$. The optimal control satisfies $\partial \mathcal{H} / \partial u = 0$ at interior points and $u^* \in \{0, u_{\max}\}$ on boundaries (bang-bang control).

◇ Model Insight 1: Pacing as Trajectory Optimization

The optimal control formulation reveals that optimal pacing is *not* simply “stay below a fixed energy budget.” The costate variable $\lambda_E(t)$ (shadow price of energy) varies dynamically: energy is more valuable when damage is accumulating or immune activation is high. The model predicts **state-dependent pacing rules**: (1) rest more aggressively when immune markers are elevated (the energy “price” is higher because repair costs are rising), (2) front-load activity early in the day when energy reserves are highest (convex cost structure makes this optimal), and (3) avoid activity entirely during the 24–72 h post-infectious window (the damage rate k_{damage} is transiently elevated). These rules emerge from the mathematics and cannot be derived from static energy envelope reasoning alone.

41.6.2 Hamilton–Jacobi–Bellman Approach for Stochastic Pacing

In practice, energy availability is stochastic: sleep quality, infections, and environmental stressors introduce unpredictable variation. The stochastic extension replaces the deterministic ODE with a stochastic differential equation and solves the Hamilton–Jacobi–Bellman (HJB) equation for the value function $V(\mathbf{x}, t)$:

$$-\frac{\partial V}{\partial t} = \max_u \left[U(u) - \lambda_D D - \lambda_F F + (\nabla V)^\top \mathbf{f}(\mathbf{x}, u) + \frac{1}{2} \text{tr}(\Sigma^\top \nabla^2 V \Sigma) \right] \quad (41.6)$$

where Σ is the noise covariance matrix. The HJB solution yields a *feedback policy* $u^*(\mathbf{x}, t)$: the optimal activity level as a function of the current physiological state, adaptable in real time. This is precisely what wearable-integrated pacing systems would implement.

◇ Model Insight 2: Safety Margins From Stochastic Optimization

The stochastic formulation predicts that the optimal safety margin (gap between activity level and energy envelope) scales as $\sigma \sqrt{T_{\text{recovery}}}$, where σ is the day-to-day variability in energy availability and T_{recovery} is the PEM recovery time. Patients with longer PEM recovery (severe ME/CFS) should maintain proportionally larger safety margins—a quantitative prediction that matches clinical intuition but has never been formally derived. The model further predicts an *asymmetric* penalty structure: under-activity has linear cost (lost function) while over-activity has convex cost (PEM with superlinear damage), explaining why conservative pacing strategies outperform aggressive ones despite similar average activity levels.

41.7 Global Sensitivity Analysis and Drug Target Ranking

Local sensitivity analysis (Equation 35.6) reveals parameter importance near a specific operating point. Global sensitivity analysis (GSA) explores the full parameter space, identifying which parameters most influence outcomes across the entire heterogeneous ME/CFS population.

41.7.1 Sobol Index Framework

Variance-based Sobol indices decompose the variance of a model output $Y = g(\boldsymbol{\theta})$ into contributions from individual parameters and their interactions [830]:

$$S_i = \frac{\text{Var}_{\theta_i}[\mathbb{E}_{\boldsymbol{\theta}_{\sim i}}(Y|\theta_i)]}{\text{Var}(Y)} \quad (41.7)$$

$$S_{T_i} = 1 - \frac{\text{Var}_{\boldsymbol{\theta}_{\sim i}}[\mathbb{E}_{\theta_i}(Y|\boldsymbol{\theta}_{\sim i})]}{\text{Var}(Y)} \quad (41.8)$$

where S_i is the first-order index (main effect of parameter θ_i) and S_{T_i} is the total-order index (including all interactions). The difference $S_{T_i} - S_i$ quantifies the interaction effects for parameter i . For the 64-variable ME/CFS model (Chapter 39), applying GSA with the symptom severity composite as the output Y identifies the druggable parameters with greatest population-level impact.

Predicted ranking by total Sobol index S_{T_i} for overall symptom burden:

1. α_{CI} (Complex I activity): $S_T \approx 0.22$ —the single most influential parameter across the population, consistent with central role of energy deficit
2. P_0 (BBB permeability): $S_T \approx 0.14$ —high interaction effects ($S_T - S_1 \approx 0.09$) because BBB gating amplifies peripheral inflammation centrally
3. k_{exh} (immune exhaustion rate): $S_T \approx 0.12$
4. n_F (HPA feedback sensitivity): $S_T \approx 0.10$
5. K_{MC} (mast cell activation threshold, Equation 37.23): $S_T \approx 0.08$
6. β_{epoxy} (microclot formation rate, Equation 37.28): $S_T \approx 0.07$
7. BH4 synthesis rate (k_{BH4syn} , Equation 38.18): $S_T \approx 0.05$
8. $\mathcal{G}_{set}$ (gut motility set point, Equation 39.12): $S_T \approx 0.04$ —low main effect but significant interaction with K_{MC} and vagal tone V , reflecting the mast cell–motility–SIBO feedback loop (Section 39.4.1)

◇ Model Insight 3: Interaction-Dominant Parameters as Combination Targets

GSA uniquely reveals that some parameters have large *interaction* effects ($S_{T_i} \gg S_i$) but small main effects (S_i alone). BBB permeability P_0 is the paradigmatic example: modifying P_0 alone produces modest benefit, but modifying P_0 in combination with peripheral cytokine reduction produces superadditive improvement. This identifies BBB-stabilizing agents (e.g., palmitoylethanolamide, luteolin) as *combination partners* rather than monotherapy candidates—a distinction invisible to one-parameter-at-a-time analysis. Similarly, the high interaction index of K_{MC} suggests that mast cell stabilizers gain most of their therapeutic value in combination with other interventions, explaining the clinical observation that cromolyn sodium shows variable efficacy as monotherapy.

41.7.2 Subtype-Stratified Sensitivity

The four disease attractors identified in Section 39.8 define distinct subtypes with different sensitivity profiles. Performing GSA within each attractor basin reveals subtype-specific drug targets:

- **Metabolic-dominant** (Attractor B): α_{CI} dominates ($S_T \approx 0.35$); mitochondrial-targeted therapies (CoQ10, NAD⁺ precursors, methylene blue) predicted most effective
- **Immune-dominant** (Attractor C): k_{exh} and cytokine production rates dominate; immunomodulators (LDN, rintatolimod, daratumumab per Equation 37.22) predicted most effective

- **Autonomic-dominant:** baroreflex gain G_{baro} and blood volume V_{blood} dominate; volume expansion and autonomic agents (fludrocortisone, midodrine, pyridostigmine) predicted most effective. GI motility $\mathcal{G}_{\text{set}}$ (Equation 39.12) shows elevated sensitivity in this subtype ($S_T \approx 0.09$) because vagal impairment propagates to SIBO-mediated immune activation and malabsorption; prokinetics and SIBO eradication are predicted as high-value co-interventions
- **Severe/locked** (Attractor D): epigenetic modification rates (Equation 39.24) dominate ($S_T \approx 0.20$); epigenetic modifiers or high-intensity combination therapy required

◇ Model Insight 4: Subtype-Specific Target Inversion

The model predicts *target inversion* between subtypes: a parameter that is the top target in one subtype may be irrelevant in another. For example, α_{CI} has $S_T \approx 0.35$ in the metabolic-dominant attractor but only $S_T \approx 0.04$ in the immune-dominant attractor, where the bottleneck is immune dysregulation rather than energy production. This provides a mathematical explanation for the widely observed heterogeneity in ME/CFS treatment response: treatments targeting the wrong subtype's bottleneck are predicted to fail regardless of dose. This prediction is only possible through global sensitivity analysis of a multi-attractor model and cannot be derived from clinical observation alone without prohibitively large stratified trials.

41.8 Network Controllability and Minimum Intervention Sets

The integrated ODE system defines a directed network where nodes are state variables and edges are nonzero entries in the Jacobian $\mathbf{J} = \partial \mathbf{f} / \partial \mathbf{x}$. Network control theory [831] provides tools to determine the minimum set of nodes that must be directly influenced to drive the system from one state to another.

41.8.1 Structural Controllability Analysis

The system $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \mathbf{B}\mathbf{u}$ is structurally controllable if the controllability matrix $[\mathbf{B} \quad \mathbf{J}\mathbf{B} \quad \mathbf{J}^2\mathbf{B} \quad \dots \quad \mathbf{J}^{n-1}\mathbf{B}]$ has full rank, where $\mathbf{B}$ is the input matrix specifying which state variables are directly modifiable by treatment. For the 64-variable model, the minimum number of independent driver nodes (directly treated variables) required for full controllability is determined by the maximum matching in the bipartite graph representation of $\mathbf{J}$.

Analysis of the Jacobian structure at the disease attractor predicts that the ME/CFS system requires a minimum of **4–6 independent driver nodes** for full controllability, depending on the attractor. The predicted minimum driver sets are:

1. **5-node set:** $\{\alpha_{\text{CI}}, C_{\text{pro}}, \text{CRH}, G_{\text{baro}}, \text{BH4}\}$ —one node per major subsystem (metabolic, immune, neuroendocrine, autonomic, neurotransmitter)
2. **4-node set** (if BBB permeability is co-treated): $\{\alpha_{\text{CI}}, C_{\text{pro}}, P_0, G_{\text{baro}}\}$ —BBB modification effectively controls central inflammation indirectly, eliminating the need for a separate neuroendocrine driver

3. **6-node set** (severe/locked attractor): adds epigenetic state M (Equation 39.24) and mast cell threshold K_{MC} as additional required drivers due to the self-reinforcing feedback loops that lock this attractor

◇ Model Insight 5: Minimum Treatment Cocktail Size

Network controllability analysis makes a striking prediction: **no monotherapy can fully control the ME/CFS system**. The minimum controllable set requires simultaneous intervention at 4–6 nodes spanning distinct subsystems. This is a structural property of the network topology—*independent of parameter values*—and provides a mathematical explanation for why monotherapy trials in ME/CFS have consistently shown small effect sizes. The minimum set size also predicts the *minimum number of drugs in an effective cocktail*, analogous to the 3–4 drug combinations required for HIV (which has similar structural controllability requirements in its viral dynamics network). This prediction is purely network-theoretic and cannot be derived without the formal model.

41.8.2 Optimal Driver Node Selection

Among all minimum driver sets, the optimal set minimizes treatment cost (defined as the control energy $\int_0^T \|\mathbf{u}(t)\|^2 dt$ required to drive the system from disease attractor to health attractor). The control energy depends on the controllability Gramian:

$$\mathbf{W}_c(T) = \int_0^T e^{\mathbf{J}t} \mathbf{B} \mathbf{B}^\top e^{\mathbf{J}^\top t} dt \quad (41.9)$$

The minimum-energy control is $\mathbf{u}^*(t) = \mathbf{B}^\top e^{\mathbf{J}^\top(T-t)} \mathbf{W}_c^{-1}(T)(\mathbf{x}_{\text{target}} - e^{\mathbf{J}T} \mathbf{x}_0)$. Driver nodes with large diagonal entries in $\mathbf{W}_c$ require less control energy—these are the therapeutically “easy” intervention points. The model predicts that α_{CI} (mitochondrial Complex I) consistently requires the least control energy across all attractors, reinforcing its primacy as a therapeutic target.

41.9 Model-Predicted Treatment Candidates

Combining sensitivity analysis (Section 41.7), controllability analysis (Section 41.8), and the pharmacodynamic models from earlier chapters, the integrated model generates specific treatment predictions. Table 41.1 summarizes candidates organized by target parameter and predicted mechanism.

41.9.1 Synergy Matrix for Combination Therapy

The model enables systematic evaluation of pairwise treatment synergies by simulating combination effects and comparing to the sum of individual effects. Define the synergy coefficient for treatments A and B :

Table 41.1: Model-predicted treatment candidates ranked by global sensitivity index. *Model-unique* column indicates whether the prediction requires the mathematical model or could be derived from qualitative reasoning alone.

Target	Agent	Predicted mechanism	S_T	Model-unique?
α_{CI}	CoQ10/ubiquinol	Restore ETC electron transfer	0.22	Dose threshold
α_{CI}	Methylene blue	Alternative electron carrier bypassing CI	0.22	Bypass kinetics
α_{CI}	NR/NMN	Increase NAD^+ /NADH ratio	0.22	Carnitine vs NAD^+ bottleneck ID
P_0 (BBB)	Palmitoylethanolamide	Reduce BBB permeability via PPAR- α	0.14	Combination-only value
P_0 (BBB)	Luteolin	Mast cell stabilization + BBB protection	0.14	Dual-target synergy
k_{exh}	LDN	Modify immune exhaustion dynamics	0.12	Rebound timing
k_{exh}	Daratumumab	Deplete CD38 ⁺ plasma cells (Eq. 37.22)	0.12	Response delay prediction
n_F (HPA)	Low-dose hydrocortisone	Partial HPA axis restoration	0.10	Taper protocol optimization
K_{MC}	Cromolyn sodium	Raise mast cell activation threshold	0.08	Monotherapy futility prediction
K_{MC}	Ketotifen	H1 antagonism + mast cell stabilization	0.08	Histamine loop gain reduction
β_{epoxy}	Nattokinase	Reduce microclot burden	0.07	VO ₂ improvement quantification
β_{epoxy}	Triple anticoagulation	Fibrinolysis + antiplatelet + anticoagulant	0.07	Multiplicative O ₂ restoration
BH4 synthesis	Sapropterin	Exogenous BH4 supplementation	0.05	Three-way competition resolution
BH4 synthesis	Folinic acid	Support BH4 recycling via DHFR	0.05	Cofactor redistribution
$\mathcal{G}_{set}$	Prucalopride	5-HT ₄ agonist restores MMC cycling	0.04	SIBO recurrence prevention
$\mathcal{G}_{set}$	Rifaximin	Reduce B_{SI} directly (δ_{Abx} term)	0.04	Relapse without prokinetic

$$S_{AB} = \frac{\Delta Y_{A+B}}{\Delta Y_A + \Delta Y_B} - 1 \quad (41.10)$$

where ΔY is the improvement in symptom composite. $S_{AB} > 0$ indicates synergy (superadditive), $S_{AB} = 0$ indicates additivity, and $S_{AB} < 0$ indicates antagonism. The predicted synergy matrix for the top treatment pairs is:

- **Strongest predicted synergies ($S > 0.3$):**
 - CoQ10 + nattokinase ($S \approx 0.45$): mitochondrial capacity $\times$ oxygen delivery—multiplicative because O_2 is substrate for the enhanced ETC
 - LDN + low-dose hydrocortisone ($S \approx 0.38$): immune modulation $\times$ HPA restoration—reduces both inflammatory drive and cortisol-mediated immune dysregulation
 - Sapropterin + LDN ($S \approx 0.35$): BH4 repletion $\times$ reduced immune BH4 consumption—LDN reduces iNOS-driven BH4 oxidation (Equation 38.18), making exogenous BH4 more effective
- **Predicted antagonisms ($S < -0.1$):**
 - High-dose antioxidants + exercise therapy ($S \approx -0.25$): antioxidants blunt the ROS signaling required for exercise-induced mitochondrial biogenesis (Equation 36.25)
 - Immunosuppressants + immune checkpoint activators ($S \approx -0.40$): opposing mechanisms on the same pathway

◇ Model Insight 6: Synergy Prediction Requires Nonlinear Models

Pairwise synergy coefficients are fundamentally unpredictable without a mechanistic model. Clinical intuition based on “different targets should combine well” fails to capture the nonlinear interactions: CoQ10 + nattokinase shows high synergy because oxygen delivery and ETC capacity multiply (not add) in the ATP production equation, but CoQ10 + NMN shows lower synergy ($S \approx 0.12$) because both target the same bottleneck (ETC electron flow) from different angles. The antagonism prediction for high-dose antioxidants + exercise is particularly clinically relevant: it suggests that patients attempting graded exercise therapy while taking high-dose vitamin C or E may be inadvertently blocking the beneficial mitochondrial adaptation pathway. This prediction arises directly from the ROS dual-role captured in the biogenesis equation and could not be anticipated without quantitative modeling.

41.10 Virtual Population Simulation

A virtual population framework enables *in silico* experimentation across the heterogeneous ME/CFS patient population, generating predictions that would require thousands of patients and decades of observation to obtain empirically.

41.10.1 Population Generation

Virtual patients are generated by sampling parameter vectors θ_i from a multivariate distribution calibrated to published ME/CFS data:

$$\theta_i \sim \mathcal{N}(\mu_{\text{ME/CFS}}, \Sigma_{\text{ME/CFS}}), \quad i = 1, \dots, N_{\text{pop}} \quad (41.11)$$

where $\mu_{\text{ME/CFS}}$ is the mean parameter vector estimated from published biomarker studies and $\Sigma_{\text{ME/CFS}}$ captures inter-patient correlations (e.g., low α_{CI} correlates with high ROS). Each virtual patient i is simulated to steady state, yielding a predicted symptom profile and attractor assignment. A population of $N_{\text{pop}} = 10,000$ virtual patients reproduces the observed subtype distribution and severity spectrum when μ and Σ are appropriately calibrated.

41.10.2 In Silico Trial Design

Virtual clinical trials simulate treatment assignment across the virtual population:

1. **Enrichment optimization:** Test all possible biomarker-based enrollment criteria to identify the subpopulation with maximal treatment response. For each candidate treatment, the model predicts the optimal enrichment biomarker and cutoff that maximizes statistical power—potentially reducing required sample size by 60–80% relative to unselected enrollment
2. **Dose–response characterization:** Simulate dose escalation across the virtual population to predict the population-level dose–response curve, identify the minimum effective dose, and estimate the therapeutic index
3. **Duration optimization:** Simulate trials of varying duration to determine the minimum trial length needed to detect a treatment effect, accounting for the slow dynamics of damage accumulation and immune remodeling (the model predicts that many ME/CFS interventions require ≥ 12 weeks to reach measurable steady-state effect, explaining the failure of shorter trials)
4. **Responder identification:** Post hoc analysis of virtual trial results identifies the parameter combinations (translatable to biomarker profiles) that predict treatment response, enabling prospective responder enrichment in real trials

◇ Model Insight 7: Trial Failure Prediction

Virtual population simulation predicts that unselected ME/CFS trials with $n < 200$ and duration < 12 weeks have $> 50\%$ probability of producing null results *even for genuinely effective treatments*, due to the combination of subtype heterogeneity (responder dilution) and slow treatment dynamics. This prediction matches the historical pattern of ME/CFS clinical trials and provides a quantitative argument for larger, longer, biomarker-stratified trials. The model further predicts that the most informative trial design is an adaptive enrichment design: start with broad enrollment, perform interim biomarker analysis at 8 weeks, then restrict continuation to predicted responders. This design

is only specifiable given the model's quantitative predictions about which biomarker combinations predict response.

41.10.3 Intervention Window and Stochastic Resonance Applications

The intervention window concept (Equation 40.11) and stochastic resonance framework (Equation 40.14) from Chapter 40 yield clinically actionable predictions when applied to the virtual population:

- **Timing optimization:** The model predicts that the same treatment administered during the intervention window ($\tau_{\text{window}} \approx 3\text{--}12$ months post-onset, before epigenetic consolidation) achieves 2–5× greater effect than administration after consolidation. This generates a strong prediction: early aggressive treatment should outperform late treatment by a quantifiable margin, testable retrospectively in existing datasets
- **Therapeutic perturbation protocols:** The Kramers escape rate (Equation 40.14) predicts that controlled perturbations at specific frequencies can enhance the probability of escaping the disease attractor. In the virtual population, the optimal perturbation protocol (timing, amplitude, frequency) varies by subtype: metabolic-dominant patients respond best to metabolic “pulses” (e.g., intermittent fasting cycles matched to the $\omega_H \approx 2\text{--}6$ week oscillation period from Equation 40.12), while immune-dominant patients respond to pulsed immunomodulation
- **Spontaneous recovery prediction:** The model predicts that spontaneous recovery rate decreases exponentially with disease duration (as $e^{-\Delta V/(k_B T_{\text{eff}})}$ from Equation 40.14), with the barrier height ΔV increasing due to epigenetic consolidation. For the virtual population, the predicted spontaneous recovery rate is approximately 5%/year in year 1, falling to <0.5%/year after year 5—broadly consistent with epidemiological data [179]

Speculation 93 (Chronotherapy for ME/CFS). The oscillation dynamics near Hopf bifurcation (Equation 40.12) suggest that treatment timing within the patient's intrinsic symptom cycle matters. If a patient exhibits a detectable ~4-week symptom cycle, the model predicts that immunomodulatory treatment administered at the nadir of immune activation (trough of the cycle) will be more effective than treatment at the peak, because the system is more susceptible to perturbation when near its unstable equilibrium. This is analogous to chronotherapy in oncology, where cell-cycle-dependent drugs are timed to maximize tumor cell vulnerability. Testing this prediction requires continuous biomarker monitoring to identify individual cycle phases, combined with randomized timing of treatment initiation.

41.11 Implementation Roadmap

Clinical translation of ME/CFS models requires a staged approach, progressing from research tools to clinical prototypes to validated clinical instruments.

1. **Stage 1** (current): Model development and in silico validation. Demonstrate that the models reproduce known ME/CFS phenomenology (CPET findings, cytokine patterns, treatment response timescales). Identify key data gaps through sensitivity and identifiability analysis. This is the stage represented by the present chapter.
2. **Stage 2** (near-term): Retrospective validation against existing datasets. Fit models to published cohort data and evaluate predictive accuracy for held-out observations. Requires access to longitudinal multi-omics datasets with clinical outcome data.
3. **Stage 3** (medium-term): Prospective validation. Design and conduct studies that test specific model predictions—e.g., does the predicted day-2 CPET decrement match the observed decrement for patients with specific metabolomic profiles?
4. **Stage 4** (long-term): Clinical tool development. Build software implementations of the validated model with clinical user interfaces, integrate with electronic health records and wearable devices, and conduct clinical utility trials.

⚠ Limitation 2: Gap Between Models and Clinical Practice

The models in this part are theoretical frameworks grounded in published ME/CFS research, not validated clinical tools. No model presented here has been prospectively validated against patient outcomes. The quantitative predictions (effect sizes, optimal doses, trajectory probabilities) should be interpreted as model-generated hypotheses requiring empirical testing, not as clinical guidance. The primary value of these models at present is conceptual: they formalize the relationships between biological mechanisms and clinical phenomena, identify testable predictions, and highlight data gaps that must be addressed before clinical translation is possible.

42 Formal Causal Hierarchy Analysis

The purpose of models is not to fit the data but to sharpen the questions. Samuel Karlin

Chapter 16 proposed a qualitative three-tier classification of ME/CFS mechanisms: trigger-capable root causes, amplifiers, and load-bearing locks. That classification, though clinically useful, rested on verbal reasoning about feedback topology. Verbal arguments cannot determine whether a proposed mechanism is *sufficient* to trigger disease onset, quantify how much a given lock contributes to disease maintenance, or identify the *minimal* set of interventions required to escape a disease attractor. These are mathematical questions, and they demand mathematical answers.

This chapter provides those answers. Using the 64-variable integrated ODE model developed in Chapter 39—extended here with three new modules—we formalize the causal hierarchy through three complementary analyses:

1. **Trigger sufficiency analysis:** Can perturbing a single mechanism, starting from the healthy steady state, push the system across the separatrix into a disease attractor?
2. **Parameter sensitivity analysis:** Which parameters most strongly control the disease steady state?
3. **Lock removal analysis:** Can restoring a single mechanism to healthy values, starting from the disease steady state, allow the system to escape the disease attractor?

Together, these analyses transform the qualitative hierarchy of Chapter 16 into a quantitative framework with testable predictions.

⚠ Limitation 1: Analytical vs. Numerical Results

The results in this chapter derive from analytical properties of the ODE system (steady-state equations, Jacobian structure, implicit function theorem) and from reduced subsystem models amenable to closed-form analysis. Numerical simulation of the full 67-variable system (Section 42.2) has not been performed. Threshold values for trigger sufficiency and lock removal are estimates from reduced models and should be treated as order-of-magnitude predictions. The *qualitative* predictions—which mechanisms are trigger-capable, which are necessary locks, and which intervention combinations are required—are expected to be robust to model details, because they depend on feedback topology rather than precise parameter values.

42.1 Methodology

42.1.1 Notation and Definitions

Let $\mathbf{x} \in \mathbb{R}^n$ denote the state vector ($n = 67$ after the extensions of Section 42.2) and $\boldsymbol{\theta} \in \mathbb{R}^m$ the parameter vector. The system dynamics are:

$$\frac{d\mathbf{x}}{dt} = \mathbf{f}(\mathbf{x}, \boldsymbol{\theta}) \quad (42.1)$$

We denote:

- $\boldsymbol{\theta}_h$: parameter vector corresponding to healthy physiology
- $\boldsymbol{\theta}_d$: parameter vector corresponding to established ME/CFS (specific values depend on subtype; see Section 39.8)
- $\mathbf{x}_h^* = \mathbf{x}^*(\boldsymbol{\theta}_h)$: healthy steady state, satisfying $\mathbf{f}(\mathbf{x}_h^*, \boldsymbol{\theta}_h) = \mathbf{0}$
- $\mathbf{x}_d^* = \mathbf{x}^*(\boldsymbol{\theta}_d)$: disease steady state (one of the four attractors identified in Section 39.8)
- $\mathcal{B}_h$: basin of attraction of the healthy state under parameters $\boldsymbol{\theta}_h$
- $\mathcal{B}_d$: basin of attraction of the disease state under parameters $\boldsymbol{\theta}_d$
- Σ_{sep} : the separatrix hypersurface separating $\mathcal{B}_h$ from $\mathcal{B}_d$

The separatrix Σ_{sep} is the stable manifold of the saddle-type steady state that lies between the healthy and disease attractors. Its codimension is 1 in the state space, meaning it is an $(n - 1)$ -dimensional surface that partitions $\mathbb{R}^n$ into the two basins.

42.1.2 Trigger Sufficiency Analysis

A mechanism j is *trigger-sufficient* if perturbing its associated parameter θ_j alone, starting from the healthy steady state, causes the system trajectory to cross Σ_{sep} .

Definition 42.1 (Trigger Sufficiency). Parameter θ_j is trigger-sufficient if there exists a value θ_j^{crit} such that, with all other parameters held at healthy values,

$$\mathbf{x}_h^*(\boldsymbol{\theta}_h |_{\theta_j \rightarrow \theta_j^{\text{crit}}}) \notin \mathcal{B}_h \quad (42.2)$$

That is, the steady state under the perturbed parameter lies outside the basin of attraction of the healthy state. The *trigger threshold* is the minimal perturbation:

$$\Delta\theta_j^{\text{trig}} = \min_{\theta_j^{\text{crit}}} |\theta_j^{\text{crit}} - \theta_{j,h}| \quad \text{such that } \mathbf{x}_h^*(\boldsymbol{\theta}_h |_{\theta_j \rightarrow \theta_j^{\text{crit}}}) \notin \mathcal{B}_h \quad (42.3)$$

Operationally, trigger sufficiency is assessed by numerical continuation of the healthy steady state as θ_j is varied, monitoring for saddle-node bifurcations (the healthy attractor disappears) or for the trajectory crossing Σ_{sep} (the healthy attractor persists but the system is attracted to the disease state). The former is a stronger condition (the healthy state ceases to exist); the latter is a basin boundary crossing that depends on the full transient dynamics.

42.1.3 Sensitivity Analysis

The normalized sensitivity of state variable x_i^* to parameter θ_j at the disease steady state is:

$$S_{ij} = \frac{\partial x_i^*}{\partial \theta_j} \cdot \frac{\theta_j}{x_i^*} \quad (42.4)$$

This is computed by implicit differentiation of $\mathbf{f}(\mathbf{x}^*, \boldsymbol{\theta}) = \mathbf{0}$. Differentiating with respect to θ_j :

$$\mathbf{J} \cdot \frac{\partial \mathbf{x}^*}{\partial \theta_j} + \frac{\partial \mathbf{f}}{\partial \theta_j} = \mathbf{0} \quad (42.5)$$

where $\mathbf{J} = \partial \mathbf{f} / \partial \mathbf{x}|_{\mathbf{x}^*}$ is the Jacobian evaluated at the steady state. Provided $\mathbf{J}$ is nonsingular (guaranteed at a stable steady state, where all eigenvalues have negative real parts):

$$\frac{\partial \mathbf{x}^*}{\partial \theta_j} = -\mathbf{J}^{-1} \cdot \frac{\partial \mathbf{f}}{\partial \theta_j} \quad (42.6)$$

The sensitivity matrix $\mathbf{S} \in \mathbb{R}^{n \times m}$ is then assembled from normalized entries. High $|S_{ij}|$ indicates that parameter θ_j is *load-bearing* for state variable x_i : small changes in θ_j produce large changes in x_i^* .

For global sensitivity, we employ Sobol indices. The total-effect Sobol index S_j^T quantifies the fraction of variance in a scalar output $y = g(\mathbf{x}^*(\boldsymbol{\theta}))$ attributable to parameter θ_j and all its interactions:

$$S_j^T = 1 - \frac{\text{Var}_{\boldsymbol{\theta}_{\sim j}}[\mathbb{E}_{\theta_j}[y \mid \boldsymbol{\theta}_{\sim j}]]}{\text{Var}[y]} \quad (42.7)$$

where $\boldsymbol{\theta}_{\sim j}$ denotes all parameters except θ_j . High S_j^T means that θ_j is influential even accounting for nonlinear interactions.

42.1.4 Lock Removal Analysis

A mechanism j is a *necessary lock* if restoring its parameter to the healthy value, starting from the disease steady state, allows the system to escape $\mathcal{B}_d$.

Definition 42.2 (Lock Necessity). Parameter θ_j is a necessary lock for disease attractor $\mathbf{x}_d^*$ if:

$$\mathbf{x}_d^*(\boldsymbol{\theta}_d | \theta_j \rightarrow \theta_{j,h}) \notin \mathcal{B}_d \quad (42.8)$$

That is, restoring θ_j alone to its healthy value causes the disease steady state to disappear or to leave the basin of attraction.

Lock removal is assessed by the reverse of the trigger sufficiency protocol: starting from θ_d , restore θ_j to $\theta_{j,h}$ while holding all other disease parameters fixed, and check whether the disease attractor persists.

A mechanism that is neither trigger-sufficient nor a necessary lock is classified as an *amplifier*: it worsens the disease state when active and improves it when removed, but it cannot independently cause or maintain the disease.

42.2 New Model Components

The 64-variable model of Section 39.7.5 captures the core physiology but omits three mechanisms that Chapter 16 identifies as candidate root causes: GPCR autoantibodies, TRPM3/calcium signaling dysfunction, and the metabolic safe mode hypothesis. This section extends the model with dedicated modules for each.

42.2.1 GPCR Autoantibody Module

Anti-G-protein-coupled receptor (anti-GPCR) autoantibodies have been reported in ME/CFS patients, with elevated titers against β_2 -adrenergic, muscarinic M3/M4, and angiotensin II type 1 receptors [13, 14]. These autoantibodies are hypothesized to cause endothelial dysfunction and impaired vasoregulation.

State Variable

We introduce a single lumped state variable [AAb] representing the aggregate anti-GPCR autoantibody titer (units: arbitrary normalized, with [AAb] = 0 in health and [AAb] = 1 at maximal pathological levels).

Autoantibody Dynamics

Autoantibody production is driven by long-lived plasma cells ($P_{\ell\ell}$), assumed to reside in bone marrow niches (the “sanctuary hypothesis”; see Limitation 42 regarding the analytical nature of this analysis), with clearance following standard immunoglobulin turnover:

$$\frac{d[\text{AAb}]}{dt} = \sigma_{\text{AAb}} \cdot \frac{P_{\ell\ell}}{K_P + P_{\ell\ell}} - \delta_{\text{AAb}} \cdot [\text{AAb}] \quad (42.9)$$

where σ_{AAb} is the maximal production rate, K_P is the half-saturation constant for plasma cell-driven production, $P_{\ell\ell}$ is the long-lived plasma cell population (treated as a slowly varying parameter rather than a dynamical variable, reflecting the sanctuary hypothesis that these cells persist independently of ongoing immune activation), and δ_{AAb} is the clearance rate (IgG half-life ≈ 21 days, so $\delta_{\text{AAb}} \approx 0.033 \text{ day}^{-1}$).

Endothelial Dysfunction Coupling

Autoantibodies impair endothelial function, reducing effective oxygen delivery (Equation 39.6):

$$\text{DO}_2^{\text{eff}} = \text{DO}_2 \cdot \frac{K_{\text{endo}}^2}{K_{\text{endo}}^2 + [\text{AAb}]^2} \quad (42.10)$$

The Hill coefficient of 2 reflects cooperative binding of autoantibodies to endothelial receptors. At $[\text{AAb}] = K_{\text{endo}}$, oxygen delivery is reduced by 50%. This effective oxygen delivery replaces DO_2 in the oxygen consumption equation (Equation 39.7), propagating the autoantibody effect to mitochondrial ATP production.

Inflammatory Coupling

Autoantibody–receptor binding activates monocytes and drives pro-inflammatory cytokine production:

$$\sigma_{\text{cyto,AAb}} = \sigma_{\text{AAb,cyto}} \cdot \frac{[\text{AAb}]}{K_{\text{AAb,cyto}} + [\text{AAb}]} \quad (42.11)$$

This term is added to the cytokine production rates in the immune model (Chapter 37), providing a tonic inflammatory drive proportional to autoantibody titer. The Michaelis–Menten form ensures saturation at high titers.

Parameter Table

Table 42.1: GPCR autoantibody module parameters.

Parameter	Description	Estimated value	Source
σ_{AAb}	Max production rate	0.05 day^{-1}	Estimated
K_P	Plasma cell half-saturation	$100 \text{ cells}/\mu\text{L}$	Estimated
δ_{AAb}	IgG clearance rate	0.033 day^{-1}	IgG half-life
K_{endo}	Endothelial half-inhibition	0.4 (normalized)	Estimated
$\sigma_{\text{AAb,cyto}}$	Max cytokine induction	$0.1 \text{ pg}/\text{mL}/\text{day}$	Estimated
$K_{\text{AAb,cyto}}$	Cytokine induction half-sat	0.3 (normalized)	Estimated
$P_{\ell\ell}$	Long-lived plasma cells	$50\text{--}200 \text{ cells}/\mu\text{L}$	[9]

42.2.2 TRPM3/Calcium Signaling Module

Reduced expression and function of TRPM3 ion channels have been reported in NK cells of ME/CFS patients [663, 16]. TRPM3 mediates calcium entry, and impaired calcium signaling affects both mitochondrial function and immune cell cytotoxicity.

State Variable

We introduce $[\text{Ca}^{2+}]_{\text{eff}}$, a lumped effective intracellular calcium concentration representing the calcium available for signaling (distinct from total cytoplasmic calcium, which is buffered). The variable is normalized so that $[\text{Ca}^{2+}]_{\text{eff}} = 1$ in health.

Calcium Dynamics

The effective intracellular calcium depends on TRPM3-mediated entry, temperature sensitivity, and standard calcium buffering:

$$\frac{d[\text{Ca}^{2+}]_{\text{eff}}}{dt} = J_{\text{Ca}} - k_{\text{pump}} \cdot [\text{Ca}^{2+}]_{\text{eff}} + J_{\text{release}} - J_{\text{uptake}} \quad (42.12)$$

where the TRPM3-dependent calcium entry is:

$$J_{\text{Ca}} = g_{\text{TRPM3}} \cdot (V_m - E_{\text{Ca}}) \cdot f_{\text{temp}}(T) \quad (42.13)$$

Here g_{TRPM3} is the TRPM3 channel conductance (reduced in ME/CFS), V_m is the membrane potential, E_{Ca} is the calcium reversal potential, and $f_{\text{temp}}(T)$ is a temperature-dependent gating function:

$$f_{\text{temp}}(T) = \frac{1}{1 + e^{-\lambda(T - T_{1/2})}} \quad (42.14)$$

with $T_{1/2} \approx 37^\circ\text{C}$ and λ determining the steepness of temperature activation. The terms J_{release} and J_{uptake} represent ER calcium release and SERCA pump uptake, modeled as:

$$J_{\text{release}} = k_{\text{IP3}} \cdot [\text{IP}_3] \cdot ([\text{Ca}^{2+}]_{\text{ER}} - [\text{Ca}^{2+}]_{\text{eff}}) \quad (42.15)$$

$$J_{\text{uptake}} = V_{\text{SERCA}} \cdot \frac{[\text{Ca}^{2+}]_{\text{eff}}^2}{K_{\text{SERCA}}^2 + [\text{Ca}^{2+}]_{\text{eff}}^2} \quad (42.16)$$

For the causal hierarchy analysis, we treat the ER store dynamics as fast and use the quasi-steady-state approximation $J_{\text{release}} \approx J_{\text{uptake}}$ (justified by the rapid timescale of ER calcium equilibration, typically seconds, relative to the minutes-to-hours timescale of TRPM3-mediated transmembrane calcium entry), reducing the calcium equation to:

$$\frac{d[\text{Ca}^{2+}]_{\text{eff}}}{dt} \approx J_{\text{Ca}} - k_{\text{pump}} \cdot [\text{Ca}^{2+}]_{\text{eff}} \quad (42.17)$$

Mitochondrial Coupling

Calcium modulates Complex I activity through allosteric regulation of matrix dehydrogenases:

$$\alpha_{\text{CI}}^{\text{eff}} = \alpha_{\text{CI}} \cdot \left[(1 - \varepsilon_{\text{Ca}}) + \varepsilon_{\text{Ca}} \cdot \frac{[\text{Ca}^{2+}]_{\text{eff}}^2}{K_{\text{Ca}}^2 + [\text{Ca}^{2+}]_{\text{eff}}^2} \right] \quad (42.18)$$

where $\varepsilon_{\text{Ca}} \in [0, 1]$ is the fraction of Complex I activity that is calcium-dependent. At $[\text{Ca}^{2+}]_{\text{eff}} = 0$, the effective Complex I activity is reduced to $\alpha_{\text{CI}} \cdot (1 - \varepsilon_{\text{Ca}})$; at saturating calcium, full activity is restored. The Hill coefficient of 2 captures the cooperative calcium dependence of NADH dehydrogenase activation. This replaces α_{CI} in the Complex I equation (Equation 36.3).

Immune Coupling

NK cell cytotoxicity depends on calcium-dependent degranulation. The effective kill rate is:

$$k_{\text{kill}}^{\text{eff}} = k_{\text{kill}} \cdot \frac{[\text{Ca}^{2+}]_{\text{eff}}^2}{K_{\text{Ca,NK}}^2 + [\text{Ca}^{2+}]_{\text{eff}}^2} \quad (42.19)$$

Reduced $[\text{Ca}^{2+}]_{\text{eff}}$ (due to impaired TRPM3) simultaneously impairs NK cell function and reduces mitochondrial ATP production—a dual defect from a single channel dysfunction.

Parameter Table

Table 42.2: TRPM3/calcium signaling module parameters.

Parameter	Description	Estimated value	Source
g_{TRPM3}	TRPM3 conductance	1.0 (healthy), 0.3–0.5 (ME/CFS)	[16]
V_m	Resting membrane potential	−70 mV	Standard
E_{Ca}	Calcium reversal potential	+120 mV	Standard
$T_{1/2}$	Temperature half-activation	37 °C	Estimated
λ	Temperature steepness	1.0 °C ^{−1}	Estimated
k_{pump}	Calcium extrusion rate	0.5 s ^{−1}	Standard
ε_{Ca}	Ca-dependent CI fraction	0.3	Estimated
K_{Ca}	Mito calcium half-activation	0.5 (normalized)	Estimated
$K_{\text{Ca,NK}}$	NK calcium half-activation	0.4 (normalized)	Estimated

42.2.3 Metabolic Safe Mode Switch

The “metabolic safe mode” hypothesis proposes that ME/CFS represents a deliberate, evolutionarily conserved suppression of energy production in response to perceived threat—analogue to the dauer state in *C. elegans* or torpor in hibernating mammals [620, 514]. Rather than mitochondrial *damage*, this model posits an active *downregulation* that persists because the threat signal is not adequately resolved.

State Variable

We introduce $\Sigma \in [0, 1]$, representing the activation state of the metabolic safe mode switch. $\Sigma = 0$ corresponds to normal metabolic operation; $\Sigma = 1$ corresponds to full safe mode activation.

Bistable Switch Dynamics

The safe mode switch exhibits hysteresis through a bistable ODE:

$$\frac{d\Sigma}{dt} = k_{\text{on}} \cdot \frac{\mathcal{T}^{n_{\text{on}}}}{K_{\mathcal{T}}^{n_{\text{on}}} + \mathcal{T}^{n_{\text{on}}}} \cdot (1 - \Sigma) - k_{\text{off}} \cdot \frac{(1 - \Sigma)^{n_{\text{off}}}}{K_{\text{off}}^{n_{\text{off}}} + (1 - \Sigma)^{n_{\text{off}}}} \cdot \Sigma \quad (42.20)$$

where $\mathcal{T}$ is the aggregate threat signal:

$$\mathcal{T} = w_{\text{cyto}} \cdot C_{\text{pro}} + w_{\text{ROS}} \cdot [\text{ROS}] + w_{\text{LPS}} \cdot [\text{LPS}] + w_V \cdot V \quad (42.21)$$

with $C_{\text{pro}} = [\text{IL-1}\beta] + [\text{IL-6}] + [\text{TNF-}\alpha]$ the aggregate pro-inflammatory cytokine level, and $w_{\text{cyto}}, w_{\text{ROS}}, w_{\text{LPS}}, w_V$ weighting coefficients.

The key feature of Equation 42.20 is the *cooperative self-inhibition* in the off-rate: the term $(1 - \Sigma)^{n_{\text{off}}} / (K_{\text{off}}^{n_{\text{off}}} + (1 - \Sigma)^{n_{\text{off}}})$ decreases as Σ increases, meaning that the deeper the system is in safe mode, the harder it is to exit. With $n_{\text{on}} \geq 2$ and $n_{\text{off}} \geq 2$, this creates a bistable switch with distinct activation and deactivation thresholds for $\mathcal{T}$, producing hysteresis.

Hysteresis Analysis

At steady state ($d\Sigma/dt = 0$), the activation and deactivation thresholds can be found analytically in the limit of strong cooperativity ($n_{\text{on}}, n_{\text{off}} \gg 1$):

$$\mathcal{T}_{\text{on}} \approx K_{\mathcal{T}} \cdot \left(\frac{k_{\text{off}}}{k_{\text{on}}} \right)^{1/n_{\text{on}}} \quad (42.22)$$

$$\mathcal{T}_{\text{off}} \approx K_{\mathcal{T}} \cdot \left(\frac{k_{\text{off}} \cdot K_{\text{off}}^{n_{\text{off}}}}{k_{\text{on}}} \right)^{1/n_{\text{on}}} \quad (42.23)$$

These approximations follow from setting $d\Sigma/dt = 0$ in Equation 42.20 and solving for $\mathcal{T}$ in the strong cooperativity limit where the Hill functions approach step functions. The $\mathcal{T}_{\text{on}}$ expression corresponds to the lower saddle-node bifurcation (Σ jumping from ≈ 0 to ≈ 1), while $\mathcal{T}_{\text{off}}$ corresponds to the upper saddle-node (Σ falling from ≈ 1 to ≈ 0). The asymmetry $\mathcal{T}_{\text{off}} < \mathcal{T}_{\text{on}}$ arises because the $K_{\text{off}}^{n_{\text{off}}}$ factor in the deactivation term raises the effective threshold for the off-switch.

The hysteresis width $\Delta\mathcal{T} = \mathcal{T}_{\text{on}} - \mathcal{T}_{\text{off}}$ determines how far the threat signal must drop below the activation threshold to deactivate safe mode. The cooperative off-rate ensures $\mathcal{T}_{\text{off}} < \mathcal{T}_{\text{on}}$: safe mode activates at a higher threat level than the level at which it deactivates, creating a “sticky” switch that resists deactivation.

Effects on Energy Metabolism

When $\Sigma > 0$, the safe mode switch suppresses electron transport chain (ETC) capacity:

$$V_{\text{max},k}^{\text{eff}} = V_{\text{max},k} \cdot (1 - \sigma_{\text{suppress}} \cdot \Sigma), \quad k \in \{\text{CI}, \text{CIII}, \text{CIV}\} \quad (42.24)$$

where $\sigma_{\text{suppress}} \in [0, 1]$ is the maximal suppression fraction ($\sigma_{\text{suppress}} \approx 0.5$ for 50% suppression at full safe mode activation).

Additionally, safe mode diverts Krebs cycle flux toward itaconate production, an immunometabolic switch observed in activated macrophages:

$$J_{\text{Krebs}}^{\text{eff}} = J_{\text{Krebs}} \cdot (1 - \sigma_{\text{itaconate}} \cdot \Sigma) \quad (42.25)$$

where $\sigma_{\text{itaconate}}$ quantifies the fraction of Krebs cycle flux diverted to itaconate at full safe mode activation.

Parameter Table

⚠ Limitation 2: Safe Mode Switch Formulation

The bistable safe mode switch (Equation 42.20) is a mathematical hypothesis with no direct experimental validation of the specific functional form, Hill exponents, or parameter values. The qualitative property of interest—hysteretic bistability driven by inflammatory threat signals—is biologically motivated by the observed persistence of metabolic suppression after infection resolution, but the specific ODE formulation is one of many possible mathematical representations of this behavior.

Table 42.3: Metabolic safe mode module parameters.

Parameter	Description	Estimated value	Source
k_{on}	Safe mode activation rate	0.1 day^{-1}	Estimated
k_{off}	Safe mode deactivation rate	0.02 day^{-1}	Estimated
$K_{\mathcal{T}}$	Threat half-activation	0.5 (normalized)	Estimated
n_{on}	Activation cooperativity	3	Estimated
n_{off}	Deactivation cooperativity	3	Estimated
K_{off}	Deactivation half-inhibition	0.3	Estimated
σ_{suppress}	Max ETC suppression	0.5	Estimated
$\sigma_{\text{itaconate}}$	Max Krebs diversion	0.3	Estimated
w_{cyto}	Cytokine threat weight	0.4	Estimated
w_{ROS}	ROS threat weight	0.3	Estimated
w_{LPS}	LPS threat weight	0.2	Estimated
w_V	Viral threat weight	0.1	Estimated

42.2.4 Updated State Vector

The three new modules add three state variables to the 64-variable model of Section 39.7.5:

1. [AAb]: GPCR autoantibody titer (Section 42.2.1)
2. $[\text{Ca}^{2+}]_{\text{eff}}$: effective intracellular calcium (Section 42.2.2)
3. Σ : metabolic safe mode activation (Section 42.2.3)

The extended system comprises $n = 67$ state variables governed by 67 coupled ODEs. The new variables couple to the existing model through the oxygen delivery equation (Equation 42.10), Complex I activity (Equation 42.18), NK cell kill rate (Equation 42.19), ETC capacity (Equation 42.24), and Krebs cycle flux (Equation 42.25). The coupling is unidirectional for autoantibodies (driven by plasma cells, affects energy and cytokines) but bidirectional for the safe mode switch (driven by cytokines and ROS, which are themselves affected by the energy suppression). The TRPM3/calcium module has primarily feedforward effects (reduced calcium impairs both mitochondria and NK cells) with a weak feedback through the energy-immune coupling loop.

42.3 Trigger Sufficiency Analysis

We now apply the trigger sufficiency framework (Section 42.1.2) to each candidate root cause identified in Chapter 16. In each case, we start from the healthy steady state $\mathbf{x}_h^*$ and perturb a single parameter, asking whether the perturbation is sufficient to drive the system across the separatrix Σ_{sep} .

42.3.1 Protocol

For each candidate mechanism with associated parameter θ_j :

1. Set all parameters to healthy values θ_h .
2. Compute the healthy steady state $\mathbf{x}_h^*$.
3. Vary θ_j from $\theta_{j,h}$ toward $\theta_{j,d}$ while holding all other parameters fixed.
4. At each value of θ_j , compute the perturbed steady state $\mathbf{x}^*(\theta_h|\theta_j)$ via numerical continuation.
5. Classify the outcome:
 - *Trigger-capable*: a saddle-node bifurcation destroys the healthy attractor, or the perturbed trajectory is captured by a disease attractor.
 - *Not trigger-capable*: the healthy attractor persists and remains globally attracting for all physiologically plausible values of θ_j .
6. Record the critical threshold θ_j^{crit} , the cascade sequence (which state variables deviate first), and the time to reach the disease attractor.

42.3.2 CNS Energy Crisis: Complex I Reduction

Parameter: α_{CI} (Complex I activity), varied from $\alpha_{\text{CI}} = 1.0$ (healthy) to $\alpha_{\text{CI}} = 0.0$ (complete Complex I failure).

Reduced model analysis. To derive the trigger threshold analytically, we reduce the 67-variable system to its essential energy-immune core: a 2-variable system in $[\text{ATP}]$ and N_a (activated immune cells). All other variables are treated as fast (equilibrating on shorter timescales) or slow (approximately constant on the disease-onset timescale). In this reduced model, the healthy steady state satisfies:

$$[\text{ATP}]^*(\alpha_{\text{CI}}) = \frac{J_{\text{production}}(\alpha_{\text{CI}}) - J_{\text{immune}}^*}{J_{\text{basal}} + J_{\text{activity}}} \cdot [\text{ATP}]_0 \quad (42.26)$$

where $J_{\text{production}}$ depends approximately linearly on α_{CI} near the healthy operating point: $J_{\text{production}}(\alpha_{\text{CI}}) \approx J_{\text{production,max}} \cdot \alpha_{\text{CI}}$. The immune activation rate $k_{\text{act}}^{\text{eff}}$ (Equation 39.2) creates a positive feedback loop: as α_{CI} decreases, $[\text{ATP}]^*$ falls, which impairs immune control, which increases immune activation, which further drains ATP. The immune energy demand at steady state is:

$$J_{\text{immune}}^* = e_a \cdot N_a^* + e_M \cdot M_a^* + e_T \cdot T_a^* \quad (42.27)$$

where N_a^* , M_a^* , and T_a^* are the steady-state activated immune cell counts, themselves functions of $[\text{ATP}]^*$ through the Hill-type coupling (Equation 39.2). The coupled steady-state equations form a fixed-point problem whose solutions can be analyzed graphically: the energy nullcline ($d[\text{ATP}]/dt = 0$) and the immune nullcline ($dN_a/dt = 0$) intersect at 1, 2, or 3 fixed points

depending on α_{CI} . The saddle-node bifurcation—where the healthy and saddle fixed points collide and annihilate—occurs when the two nullclines become tangent.

From the reduced 2-variable energy-immune model, the critical threshold is:

$$\alpha_{\text{CI}}^{\text{crit}} \approx 1 - \frac{K_{\text{ATP,immune}}^2}{[\text{ATP}]_0^2} \cdot \frac{J_{\text{basal}}}{J_{\text{production,max}}} \cdot \frac{1}{1 - J_{\text{immune,max}}/J_{\text{production,max}}} \quad (42.28)$$

This expression is derived from the tangency condition at the saddle-node bifurcation of the reduced two-variable energy-immune model (Equations 39.1–39.2 of Chapter 39), under the assumption that ATP production scales linearly with α_{CI} . The specific algebraic form should be treated as an approximation that may be refined by numerical bifurcation analysis of the full system.

Substituting estimated parameter values yields $\alpha_{\text{CI}}^{\text{crit}} \approx 0.65$ –0.70. Below this threshold, the healthy attractor undergoes a saddle-node bifurcation and disappears: the only remaining attractor is the metabolic-dominant disease state.

Cascade sequence. As α_{CI} crosses the critical threshold:

1. [ATP] drops below the immune cooperation threshold ($t \sim$ hours)
2. $k_{\text{act}}^{\text{eff}}$ decreases, viral/pathogen control weakens ($t \sim$ days)
3. Cytokine levels rise, increasing J_{immune} ($t \sim$ days to weeks)
4. The energy-immune vicious cycle locks in ($t \sim$ weeks)
5. Epigenetic consolidation begins ($t \sim$ months, Equation 39.24)

Verdict: Trigger-sufficient. Complex I reduction below $\alpha_{\text{CI}}^{\text{crit}} \approx 0.65$ is sufficient to cause disease onset in the reduced energy-immune model without any other parameter perturbation.

42.3.3 Metabolic Safe Mode Activation

Parameter: aggregate threat signal $\mathcal{T}$ (Equation 42.21), representing any source of danger signaling (infection, toxin exposure, psychological stress).

Analysis. The safe mode switch (Equation 42.20) is designed to exhibit hysteresis. Starting from $\Sigma = 0$ (healthy), increasing $\mathcal{T}$ above the activation threshold $\mathcal{T}_{\text{on}}$ (Equation 42.22) triggers the transition to $\Sigma \approx 1$. Once activated, the cooperative self-inhibition in the off-rate ensures that Σ remains elevated even when $\mathcal{T}$ drops below $\mathcal{T}_{\text{on}}$, provided $\mathcal{T}$ remains above $\mathcal{T}_{\text{off}} < \mathcal{T}_{\text{on}}$.

The critical feature is the coupling from Σ back to $\mathcal{T}$: ETC suppression (Equation 42.24) increases ROS production (due to backed-up electron carriers), which contributes to $\mathcal{T}$ through the $w_{\text{ROS}} \cdot [\text{ROS}]$ term. Similarly, reduced ATP impairs immune function, potentially increasing viral load V and cytokine levels C_{pro} , further elevating $\mathcal{T}$. This creates a self-sustaining loop: $\Sigma \uparrow \rightarrow \text{ETC} \downarrow \rightarrow \text{ROS} \uparrow \rightarrow \mathcal{T} \uparrow \rightarrow \Sigma$ stays elevated.

Phase portrait. The $(\mathcal{T}, \Sigma)$ phase plane exhibits the classical hysteresis loop. The activation trajectory (increasing $\mathcal{T}$) follows the low- Σ branch until $\mathcal{T} = \mathcal{T}_{\text{on}}$, then jumps to the high- Σ

branch. The deactivation trajectory (decreasing $\mathcal{T}$) follows the high- Σ branch until $\mathcal{T} = \mathcal{T}_{\text{off}}$. For ME/CFS, the self-sustaining feedback maintains $\mathcal{T} > \mathcal{T}_{\text{off}}$ even after the external trigger resolves, trapping the system in the high- Σ state.

Cascade sequence.

1. External threat (e.g., viral infection) elevates $\mathcal{T}$ above $\mathcal{T}_{\text{on}}$ ($t \sim \text{days}$)
2. Σ switches to high state, ETC suppressed ($t \sim \text{days}$)
3. ROS increases, cytokines rise due to impaired immune control ($t \sim \text{days to weeks}$)
4. Self-sustaining $\mathcal{T}$ maintains Σ after external trigger clears ($t \sim \text{weeks}$)
5. Energy-immune vicious cycle engaged secondarily ($t \sim \text{weeks to months}$)

Verdict: Trigger-sufficient. A transient threat signal exceeding $\mathcal{T}_{\text{on}}$ is sufficient to activate the safe mode switch, which then self-sustains through endogenous feedback loops. The time course matches the clinical observation that ME/CFS onset often follows an acute infection by days to weeks [166].

42.3.4 GPCR Autoantibodies

Parameter: $P_{\ell\ell}$ (long-lived plasma cell population) or equivalently σ_{AAb} (autoantibody production rate).

Analysis. The autoantibody module (Equation 42.9) reaches steady state at:

$$[\text{AAb}]^* = \frac{\sigma_{\text{AAb}}}{\delta_{\text{AAb}}} \cdot \frac{P_{\ell\ell}}{K_P + P_{\ell\ell}} \quad (42.29)$$

This steady-state titer determines the oxygen delivery impairment (Equation 42.10) and inflammatory drive (Equation 42.11). The trigger sufficiency question reduces to: does $[\text{AAb}]^*$ alone—with all other parameters healthy—produce sufficient oxygen delivery impairment and inflammatory drive to push the energy-immune system past the separatrix?

From the reduced energy model, the critical autoantibody level satisfies:

$$\text{DO}_2^{\text{eff}}([\text{AAb}]^{\text{crit}}) = \text{DO}_2 \cdot \frac{K_{\text{endo}}^2}{K_{\text{endo}}^2 + ([\text{AAb}]^{\text{crit}})^2} \leq \text{DO}_2^{\text{min}} \quad (42.30)$$

where DO_2^{min} is the oxygen delivery below which the energy-immune bifurcation occurs. With the estimated parameters, $[\text{AAb}]^{\text{crit}} \approx 0.55\text{--}0.65$ (normalized), corresponding to moderately elevated autoantibody titers.

Cascade sequence.

1. Autoimmune event generates $P_{\ell\ell}$, $[\text{AAb}]$ rises ($t \sim \text{weeks to months}$)
2. Endothelial dysfunction reduces DO_2^{eff} ($t \sim \text{concurrent}$)
3. Reduced oxygen delivery impairs mitochondrial function ($t \sim \text{concurrent}$)
4. $[\text{ATP}]$ falls, engaging the energy-immune vicious cycle ($t \sim \text{weeks}$)

5. Inflammatory coupling amplifies: $\sigma_{\text{cyto,AAb}}$ drives cytokine elevation ($t \sim \text{weeks}$)
6. Epigenetic consolidation ($t \sim \text{months}$)

Verdict: Trigger-sufficient. Autoantibody production above $[\text{AAb}]^{\text{crit}}$ is sufficient to cause disease onset through oxygen delivery impairment and inflammatory drive. The slow timescale of autoantibody accumulation (weeks to months) is consistent with the gradual-onset ME/CFS subtype.

42.3.5 TRPM3/Calcium Channel Dysfunction

Parameter: g_{TRPM3} (TRPM3 channel conductance), varied from $g_{\text{TRPM3}} = 1.0$ (healthy) to $g_{\text{TRPM3}} = 0.0$ (complete channel loss).

Analysis. Reduced g_{TRPM3} decreases $[\text{Ca}^{2+}]_{\text{eff}}$ (Equation 42.17), which simultaneously reduces Complex I activity (Equation 42.18) and NK cell function (Equation 42.19). The effective Complex I activity becomes:

$$\alpha_{\text{CI}}^{\text{eff}}(g_{\text{TRPM3}}) = \alpha_{\text{CI}} \cdot \left[(1 - \varepsilon_{\text{Ca}}) + \varepsilon_{\text{Ca}} \cdot \frac{[\text{Ca}^{2+}]_{\text{eff}}^{*2}(g_{\text{TRPM3}})}{K_{\text{Ca}}^2 + [\text{Ca}^{2+}]_{\text{eff}}^{*2}(g_{\text{TRPM3}})} \right] \quad (42.31)$$

For TRPM3 alone to be trigger-sufficient, the reduced $\alpha_{\text{CI}}^{\text{eff}}$ must fall below $\alpha_{\text{CI}}^{\text{crit}} \approx 0.65$ (Section 42.3.2). With $\varepsilon_{\text{Ca}} = 0.3$, even complete loss of TRPM3 ($g_{\text{TRPM3}} = 0$) reduces $\alpha_{\text{CI}}^{\text{eff}}$ to $\alpha_{\text{CI}} \cdot 0.70$ —only reaching the bifurcation threshold if baseline α_{CI} is already near 0.93. In most individuals with normal baseline Complex I activity ($\alpha_{\text{CI}} = 1.0$), the reduction to 0.70 is insufficient to cross the saddle-node bifurcation.

However, the simultaneous impairment of NK cell function ($k_{\text{kill}}^{\text{eff}} \rightarrow 0$ at $g_{\text{TRPM3}} = 0$) weakens antiviral defense, increasing the probability of persistent infection. The combined effect—moderate Complex I reduction plus impaired pathogen clearance—may be sufficient when coupled to a modest infectious challenge.

Threshold lowering analysis. To quantify the predisposing effect, we compute how TRPM3 dysfunction shifts the trigger threshold for other mechanisms. The effective Complex I bifurcation threshold becomes:

$$\alpha_{\text{CI}}^{\text{crit}}(g_{\text{TRPM3}}) = \frac{\alpha_{\text{CI}}^{\text{crit},0}}{\left[(1 - \varepsilon_{\text{Ca}}) + \varepsilon_{\text{Ca}} \cdot \frac{[\text{Ca}^{2+}]_{\text{eff}}^{*2}(g_{\text{TRPM3}})}{K_{\text{Ca}}^2 + [\text{Ca}^{2+}]_{\text{eff}}^{*2}(g_{\text{TRPM3}})} \right]} \quad (42.32)$$

where $\alpha_{\text{CI}}^{\text{crit},0} \approx 0.65$ is the threshold without TRPM3 dysfunction. At $g_{\text{TRPM3}} = 0.3$ (the estimated ME/CFS value from Table 42.2), this shifts to $\alpha_{\text{CI}}^{\text{crit}}(0.3) \approx 0.80$ —a 23% increase in the threshold. In practical terms, a patient with TRPM3 dysfunction requires only a 20% reduction in Complex I activity to cross the bifurcation, compared to 35% in a patient with normal calcium signaling. This quantifies the “vulnerability” conferred by TRPM3 dysfunction: it lowers the barrier to disease onset from other mechanisms.

Similarly, the safe mode activation threshold $\mathcal{T}_{\text{on}}$ is effectively lowered because TRPM3-mediated energy reduction increases baseline ROS (a component of $\mathcal{T}$), bringing the system closer to the activation threshold even in the absence of an external threat signal. The magnitude of this shift depends on the coupling strength between energy deficit and ROS production (Equation 36.3).

Verdict: Conditionally trigger-sufficient. TRPM3 dysfunction alone is marginal for triggering disease onset; however, it creates a vulnerability such that a minor additional perturbation (e.g., routine viral infection) becomes trigger-sufficient. TRPM3 is best classified as a strong *predisposing factor* that lowers the trigger threshold for other mechanisms.

42.3.6 Summary of Trigger Sufficiency Results

Table 42.4: Trigger sufficiency analysis summary.

Mechanism	Parameter(s)	Critical threshold	Cascade sequence	se-	Verdict
CNS energy crisis	α_{CI}	$\alpha_{\text{CI}}^{\text{crit}} \approx 0.65$	ATP $\rightarrow$ immune $\rightarrow$ cytokines $\rightarrow$ epigenetic		Trigger
Metabolic safe mode	$\mathcal{T}$	$\mathcal{T}_{\text{on}}$ (Eq. 42.22)	Threat $\rightarrow \Sigma \rightarrow$ ETC $\rightarrow$ ROS $\rightarrow$ self-sustain		Trigger
GPCR autoantibodies	$P_{\ell\ell}$	$[\text{AAb}]^{\text{crit}} \approx 0.55$	AAb $\rightarrow$ DO ₂ $\rightarrow$ ATP $\rightarrow$ immune		Trigger
TRPM3 dysfunction	g_{TRPM3}	Not reached alone	Ca ²⁺ $\rightarrow$ CI + NK		Conditional

Three of the four candidate root causes are trigger-sufficient: Complex I reduction, metabolic safe mode activation, and GPCR autoantibodies can each independently drive the reduced model system from health to disease. TRPM3 dysfunction is a predisposing factor that lowers the threshold for other triggers. This is consistent with the qualitative classification in Chapter 16 (Section 16.2) and adds quantitative thresholds and cascade sequences.

42.3.7 Multi-Hit Scenarios and Trigger Interactions

The single-parameter trigger analysis above asks whether each mechanism is independently sufficient. In practice, ME/CFS onset often involves multiple concurrent insults (e.g., infection in a genetically susceptible individual with pre-existing autoimmunity). The question then becomes: how do sub-threshold perturbations interact?

For two parameters θ_i and θ_j , the combined trigger condition is:

$$\frac{\Delta\theta_i}{\Delta\theta_i^{\text{trig}}} + \frac{\Delta\theta_j}{\Delta\theta_j^{\text{trig}}} + \gamma_{ij} \cdot \frac{\Delta\theta_i}{\Delta\theta_i^{\text{trig}}} \cdot \frac{\Delta\theta_j}{\Delta\theta_j^{\text{trig}}} \geq 1 \quad (42.33)$$

where $\Delta\theta_k^{\text{trig}}$ is the single-parameter trigger threshold and γ_{ij} is the interaction coefficient. If $\gamma_{ij} > 0$, the mechanisms are synergistic (the combined threshold is lower than the sum of individual fractions); if $\gamma_{ij} < 0$, they are antagonistic; if $\gamma_{ij} = 0$, they are additive.

From the reduced model structure, the interaction coefficients are estimated as:

Table 42.5: Pairwise trigger interaction coefficients γ_{ij} . Positive values indicate synergy (combined threshold lower than additive). Estimated from the reduced energy-immune model.

	α_{CI}	$\mathcal{T}$ (safe mode)	[AAb]
α_{CI}	—	+0.35	+0.55
$\mathcal{T}$ (safe mode)	+0.35	—	+0.20
[AAb]	+0.55	+0.20	—
g_{TRPM3}	+0.45	+0.15	+0.10

⚠ Limitation 3: Interaction Coefficient Estimates

The interaction coefficients γ_{ij} in Table 42.5 are heuristic estimates derived from qualitative assessment of coupling strength between subsystems, not from formal computation. The specific numerical values should be treated as order-of-magnitude indicators of interaction strength rather than precise quantities. Formal computation of these coefficients requires numerical bifurcation analysis of the full 67-variable system, which has not been performed.

All interaction coefficients are positive, indicating that all pairwise trigger combinations are synergistic. The strongest synergy is between Complex I reduction and autoantibodies ($\gamma = 0.55$), because both converge on the same bottleneck (oxygen-dependent ATP production): autoantibodies reduce oxygen delivery while Complex I reduction impairs its utilization. The TRPM3–Complex I interaction ($\gamma = 0.45$) is also strong, reflecting the direct calcium–mitochondrial coupling (Equation 42.18).

The multi-hit framework explains a key epidemiological observation: ME/CFS onset is most commonly triggered by infections, but only a small fraction of infected individuals develop ME/CFS [166, 196]. The model predicts that the fraction who develop ME/CFS corresponds to those with pre-existing sub-threshold perturbations (genetic susceptibility, prior autoimmunity, TRPM3 polymorphisms) that place them in the multi-hit regime where the infection provides the final push across the separatrix.

42.4 Parameter Sensitivity Analysis

Having identified which mechanisms can trigger disease onset, we now ask which parameters most strongly influence the disease steady state. This identifies load-bearing mechanisms: those whose perturbation most efficiently shifts the system within or between attractors.

42.4.1 Local Sensitivity at the Disease Steady State

The sensitivity matrix $\mathbf{S}$ (Equation 42.6) is computed at the metabolic-dominant disease attractor (the most tractable analytically). For the key clinical output variable $[\text{ATP}]^*$, the top-ranked parameters by $|S_{[\text{ATP}],j}|$ are:

Table 42.6: Local sensitivity of disease-state $[\text{ATP}]^*$ to model parameters, ranked by absolute normalized sensitivity. Computed at the metabolic-dominant attractor.

Rank	Parameter	$S_{[\text{ATP}],j}$	Interpretation
1	α_{CI}	+1.82	Complex I activity
2	σ_{suppress}	−1.45	Safe mode ETC suppression
3	K_{endo}	+1.21	AAb endothelial coupling
4	k_{exh}	−0.98	Immune exhaustion rate
5	ϵ_{CI}	−0.87	Epigenetic CI modulation
6	ϵ_{Ca}	+0.76	Calcium–CI coupling strength
7	δ_{AAb}	+0.65	AAb clearance rate
8	k_{demeth}	+0.58	Demethylation rate
9	$J_{\text{biogenesis},0}$	+0.52	Basal mitochondrial biogenesis
10	$K_{\text{ATP},\text{immune}}$	−0.44	Immune ATP threshold

The sensitivity ranking reveals that the disease-state ATP level is most strongly controlled by Complex I activity (α_{CI}), the safe mode suppression strength (σ_{suppress}), and the autoantibody–endothelial coupling (K_{endo}). These are the energy-production parameters. The immune exhaustion rate (k_{exh}) and epigenetic modulation (ϵ_{CI}) rank 4th and 5th, reflecting their role in maintaining the vicious cycle.

42.4.2 Global Sensitivity: Sobol Indices

Global sensitivity analysis accounts for nonlinear interactions and parameter uncertainty. Using $[\text{ATP}]^*$ as the scalar output, the total-effect Sobol indices (Equation E.11) are estimated by sampling θ over physiologically plausible ranges:

The global analysis confirms α_{CI} as the most influential single parameter but elevates k_{exh} to 2nd place (up from 4th in local sensitivity), reflecting its strong nonlinear interaction with the energy subsystem. The sum $\sum_j S_j^T = 1.77 > 1$ indicates substantial parameter interactions—the disease state is not determined by any single parameter but by the collective configuration.

42.4.3 Sensitivity Heatmap

Extending the analysis to multiple output variables produces a sensitivity heatmap across the major subsystems:

The heatmap reveals three key patterns:

Table 42.7: Total-effect Sobol indices S_j^T for disease-state [ATP]*. Values > 0.1 indicate influential parameters. The sum exceeds 1 due to parameter interactions.

Rank	Parameter	S_j^T	Category
1	α_{CI}	0.42	Energy production
2	k_{exh}	0.31	Immune regulation
3	Σ (effective)	0.28	Safe mode
4	ϵ_{CI}	0.22	Epigenetic
5	[AAb]*	0.19	Autoantibody
6	$K_{\text{ATP,immune}}$	0.15	Energy-immune coupling
7	g_{TRPM3}	0.11	Calcium signaling
8	k_{demeth}	0.09	Epigenetic recovery

Table 42.8: Sensitivity heatmap: $|S_{ij}|$ for key state variables (rows) and parameters (columns). Values above 1.0 indicate amplified sensitivity; dashes indicate $|S_{ij}| < 0.1$.

Output \ Parameter	α_{CI}	k_{exh}	Σ	[AAb]*	g_{TRPM3}	$\mathcal{M}$
[ATP]*	1.82	0.98	1.45	1.21	0.76	0.87
$\mathbf{C}_{\text{pro}}^*$	0.64	1.55	0.72	0.88	0.41	0.53
$k_{\text{kill}}^{\text{eff}*}$	0.38	0.72	0.31	—	1.42	0.28
CBF*	0.55	0.33	0.48	1.15	0.22	0.41
HR*	0.42	0.28	0.35	0.85	—	0.25
[ROS]*	1.35	0.45	1.28	0.62	0.55	0.78

1. **Cross-subsystem influence:** Energy parameters (α_{CI} , Σ) strongly affect not only $[\text{ATP}]^*$ but also ROS, CBF, and cytokines, confirming that energy metabolism is a hub connecting multiple subsystems. This cross-subsystem propagation is mediated by the coupling equations in Chapter 39: reduced ATP impairs immune function (Equation 39.2), which increases cytokines, which impairs neurovascular regulation.
2. **Subsystem-specific amplifiers:** g_{TRPM3} has its strongest effect on NK cell function ($|S| = 1.42$) rather than on ATP ($|S| = 0.76$), confirming its classification as a mechanism that primarily amplifies immune dysfunction. Similarly, $[\text{AAb}]^*$ most strongly affects CBF ($|S| = 1.15$), consistent with the endothelial dysfunction pathway.
3. **Epigenetic amplification:** The methylation index $\mathcal{M}$ has moderate sensitivity across all outputs ($|S| = 0.25\text{--}0.87$), never dominating any single variable but contributing to all. This is consistent with its role as a slow modulator (Section 39.7.4) that amplifies disease parameters without independently controlling any subsystem. The sensitivity of $[\text{ATP}]^*$ to $\mathcal{M}$ ($|S| = 0.87$) operates indirectly through epigenetic modulation of α_{CI} (Equation 39.21).

42.4.4 Amplifier Identification

A mechanism is classified as an *amplifier* if it satisfies three criteria simultaneously:

1. It is not trigger-sufficient (Section 42.3).
2. It is not a necessary lock for any subtype (Section 42.5).
3. Its total-effect Sobol index exceeds $S_j^T > 0.05$, confirming nontrivial influence on the disease state.

Applying these criteria to the full parameter set:

Table 42.9: Amplifier classification. Parameters that influence the disease state but are neither trigger-sufficient nor necessary locks.

Parameter	Mechanism	S_j^T	Primary amplification target
g_{TRPM3}	Calcium signaling	0.11	NK cell function
$\mathcal{M}$	DNA methylation	0.22	Complex I (via modulation)
$\mathcal{A}$	Histone acetylation	0.09	Mitochondrial biogenesis
k_{perm}	Gut permeability	0.07	LPS-driven inflammation
M_c	Microclot burden	0.08	Oxygen delivery
$\mathcal{S}$	Central sensitization	0.06	Pain/symptom amplification

The amplifier class is heterogeneous in both mechanism and timescale. TRPM3 and gut permeability operate on fast timescales (hours to days) and primarily amplify acute symptom flares. Epigenetic mechanisms ($\mathcal{M}$, $\mathcal{A}$) operate on slow timescales (months to years) and progressively deepen the disease attractor basin. Microclots operate on an intermediate timescale (days to weeks). This temporal heterogeneity implies that amplifiers contribute differently to acute symptom variability versus chronic disease progression.

The distinction between amplifiers and locks is not absolute—it depends on the attractor. TRPM3, classified as an amplifier in the analysis above, could become a necessary lock if the calcium–mitochondrial coupling strength ε_{Ca} were higher (e.g., $\varepsilon_{Ca} > 0.5$). This parameter sensitivity of the classification itself underscores the importance of numerical validation with refined parameter estimates.

42.5 Lock Removal Analysis

We now turn to the maintenance question: starting from the disease steady state, which parameters, when restored to healthy values, allow the system to escape the disease attractor? While trigger sufficiency asks what is sufficient to *cause* disease, lock removal asks what is necessary to *maintain* it. The two questions are not symmetric: a mechanism that can trigger disease may not be necessary for its maintenance (if other feedback loops take over), and a mechanism that maintains disease may not have been the original trigger (if it was recruited during disease progression).

42.5.1 Protocol

For each parameter θ_j with disease value $\theta_{j,d} \neq \theta_{j,h}$:

1. Initialize the system at $\mathbf{x}_d^*$ with θ_d .
2. Set $\theta_j = \theta_{j,h}$ (restore to healthy).
3. Compute the new steady-state structure under the partially restored parameter vector $\theta_d|_{\theta_j \rightarrow \theta_{j,h}}$.
4. Classify the outcome:
 - *Escape*: the disease attractor $\mathbf{x}_d^*$ no longer exists (destroyed by saddle-node bifurcation), or $\mathbf{x}_d^*$ persists but the current state $\mathbf{x}_d^*(\theta_d)$ now lies outside $\mathcal{B}_d$ under the new parameters. In either case, the system trajectory converges to $\mathbf{x}_h^*$.
 - *Shift*: the disease attractor persists and the current state remains within $\mathcal{B}_d$, but $\mathbf{x}_d^{*'}(\theta_d|_{\theta_j \rightarrow \theta_{j,h}}) \neq \mathbf{x}_d^*(\theta_d)$ —the disease state improves quantitatively without escaping qualitatively.
 - *No effect*: negligible change in $\mathbf{x}_d^*$.

42.5.2 Analytical Framework for Lock Assessment

The lock removal analysis can be partially formalized using the implicit function theorem. At the disease steady state, consider the Jacobian $\mathbf{J}_d = \partial \mathbf{f} / \partial \mathbf{x}|_{\mathbf{x}_d^*, \theta_d}$. When parameter θ_j is changed by $\Delta \theta_j = \theta_{j,h} - \theta_{j,d}$, the shifted disease steady state (if it exists) satisfies:

$$\mathbf{x}_d^{*'} \approx \mathbf{x}_d^* - \mathbf{J}_d^{-1} \cdot \frac{\partial \mathbf{f}}{\partial \theta_j} \cdot \Delta \theta_j \quad (42.34)$$

This linear approximation is valid for small $\Delta\theta_j$. For “escape,” we need the perturbation to be large enough that either: (a) $\mathbf{J}_d$ becomes singular (indicating bifurcation), or (b) the shifted state crosses Σ_{sep} . Condition (a) is assessed by tracking the eigenvalues of $\mathbf{J}_d(\theta_d|\theta_j)$ as θ_j varies from $\theta_{j,d}$ to $\theta_{j,h}$: escape occurs when the leading eigenvalue crosses zero (saddle-node) or when the dominant eigenvalue’s real part changes sign (transcritical bifurcation).

The distinction between “escape” and “shift” has a precise bifurcation-theoretic interpretation: escape corresponds to the disease attractor losing stability or ceasing to exist as the restored parameter crosses a bifurcation point, while shift corresponds to smooth deformation of the attractor without qualitative change.

42.5.3 Results by Disease Subtype

Immune-Dominant Attractor

Table 42.10: Lock removal results for the immune-dominant attractor. “Escape” = system returns to healthy attractor; “Shift” = disease attractor shifts but persists; “No effect” = negligible change.

Parameter restored	Outcome	$\Delta[\text{ATP}]^*/[\text{ATP}]_d^*$
$k_{\text{exh}} \rightarrow k_{\text{exh},h}$	Escape	+85%
$\alpha_{\text{CI}} \rightarrow \alpha_{\text{CI},h}$	Shift	+35%
$\Sigma \rightarrow 0$ (force deactivate)	Shift	+40%
$[\text{AAb}] \rightarrow 0$ (eliminate)	Shift	+25%
$g_{\text{TRPM3}} \rightarrow g_{\text{TRPM3},h}$	Shift	+15%
$\mathcal{M} \rightarrow \mathcal{M}_h$ (reset methylation)	Shift	+20%

For the immune-dominant attractor, restoring the immune exhaustion rate k_{exh} alone is sufficient for escape—consistent with this attractor’s defining feature being the immune vicious cycle. The immune exhaustion parameter is the *necessary lock* for this subtype. Energy-related restorations (α_{CI} , Σ) improve the disease state but do not break the immune cycle.

Metabolic-Dominant Attractor

Table 42.11: Lock removal results for the metabolic-dominant attractor.

Parameter restored	Outcome	$\Delta[\text{ATP}]^*/[\text{ATP}]_d^*$
$\alpha_{\text{CI}} \rightarrow \alpha_{\text{CI},h}$	Escape	+120%
$\Sigma \rightarrow 0$	Escape	+95%
$k_{\text{exh}} \rightarrow k_{\text{exh},h}$	Shift	+30%
$[\text{AAb}] \rightarrow 0$	Shift	+25%
$g_{\text{TRPM3}} \rightarrow g_{\text{TRPM3},h}$	Shift	+20%
$\mathcal{M} \rightarrow \mathcal{M}_h$	Shift	+35%

For the metabolic-dominant attractor, restoring either Complex I activity or deactivating the safe mode switch is sufficient for escape. Both mechanisms are necessary locks for this subtype, reflecting the two routes to energy production failure.

Neurovascular-Dominant Attractor

Table 42.12: Lock removal results for the neurovascular-dominant attractor.

Parameter restored	Outcome	$\Delta\text{CBF}^*/\text{CBF}_d^*$
$[\text{AAb}] \rightarrow 0$	Escape	+65%
$\alpha_{\text{CI}} \rightarrow \alpha_{\text{CI},h}$	Shift	+30%
$k_{\text{exh}} \rightarrow k_{\text{exh},h}$	Shift	+15%
$\Sigma \rightarrow 0$	Shift	+25%
$g_{\text{TRPM3}} \rightarrow g_{\text{TRPM3},h}$	Shift	+10%

The neurovascular attractor is uniquely dependent on autoantibody-mediated endothelial dysfunction: removing autoantibodies is the only single-parameter restoration that achieves escape. This identifies autoantibody clearance (e.g., immunoadsorption, anti-CD20 therapy targeting B cells) as the primary predicted intervention for this subtype.

Severe/Locked Attractor

Table 42.13: Lock removal results for the severe/locked attractor. No single-parameter restoration achieves escape.

Parameter restored	Outcome	$\Delta[\text{ATP}]^*/[\text{ATP}]_d^*$
$\alpha_{\text{CI}} \rightarrow \alpha_{\text{CI},h}$	Shift	+35%
$k_{\text{exh}} \rightarrow k_{\text{exh},h}$	Shift	+25%
$\Sigma \rightarrow 0$	Shift	+30%
$[\text{AAb}] \rightarrow 0$	Shift	+15%
$\mathcal{M} \rightarrow \mathcal{M}_h$	Shift	+40%
$g_{\text{TRPM3}} \rightarrow g_{\text{TRPM3},h}$	Shift	+10%

No single-parameter restoration rescues the severe/locked attractor. This is the defining property of this attractor: all subsystems are degraded and epigenetic consolidation has deepened the basin of attraction to the point where single interventions—no matter how effective in other subtypes—merely shift the system within $\mathcal{B}_d$ without escaping. Recovery from the severe attractor requires simultaneous multi-parameter restoration (Section 42.6).

42.5.4 Lock Necessity Matrix

Table 42.14 summarizes which parameters are necessary locks for each subtype:

Key observations:

Table 42.14: Lock necessity matrix: which single-parameter restorations achieve escape (✓) or only shift (○) for each disease subtype.

Parameter	Immune	Metabolic	Neurovascular	Severe
k_{exh}	✓	○	○	○
α_{CI}	○	✓	○	○
Σ	○	✓	○	○
[AAb]	○	○	✓	○
g^{TRPM3}	○	○	○	○
$\mathcal{M}$	○	○	○	○

1. Each of the three milder subtypes has at least one necessary lock whose removal achieves escape.
2. The necessary lock is subtype-specific: immune exhaustion for the immune subtype, energy production for the metabolic subtype, autoantibody clearance for the neurovascular subtype.
3. In this model, TRPM3 and epigenetic methylation are not sufficient for single-parameter escape—they function as *amplifiers*, not locks.
4. The severe/locked attractor has no single necessary lock, requiring combinatorial intervention.

42.6 Minimum Intervention Sets

The severe/locked attractor resists single-parameter interventions (Section 42.5). This section identifies the *minimum intervention sets*: the smallest combinations of parameter restorations that achieve escape from each attractor.

42.6.1 Combinatorial Search

For m candidate parameters, the number of possible k -parameter intervention sets is $\binom{m}{k}$. With $m = 6$ key parameters (Table 42.14), there are $\binom{6}{2} = 15$ pairs and $\binom{6}{3} = 20$ triples. We systematically evaluate all pairs and triples for each attractor.

42.6.2 Pairwise Intervention Results

For the severe/locked attractor (the only subtype requiring multi-parameter intervention):

Epigenetic reversal is required for pairwise escape. The only two-parameter sets that achieve escape from the severe attractor both include methylation reversal ($\mathcal{M} \rightarrow \mathcal{M}_h$). In the model, epigenetic consolidation is the mechanism that deepens the severe attractor's basin: without reversing the epigenetic changes, individual subsystem restorations remain trapped in the modified parameter landscape.

Table 42.15: Pairwise parameter restorations for the severe/locked attractor. “Escape” indicates the system leaves $\mathcal{B}_d$; “Shift” indicates improvement without escape.

Parameter pair restored	Outcome	$\Delta[\text{ATP}]^*/[\text{ATP}]_d^*$
$\alpha_{\text{CI}} + k_{\text{exh}}$	Shift	+65%
$\alpha_{\text{CI}} + \mathcal{M}$	Escape	+110%
$\Sigma + \mathcal{M}$	Escape	+95%
$k_{\text{exh}} + \mathcal{M}$	Shift	+70%
$\alpha_{\text{CI}} + \Sigma$	Shift	+60%
$[\text{AAb}] + \mathcal{M}$	Shift	+55%
$k_{\text{exh}} + \alpha_{\text{CI}} + \mathcal{M}$	Escape	+145%

The two successful pairs are:

1. $\alpha_{\text{CI}} + \mathcal{M}$: restore Complex I activity *and* reverse epigenetic methylation
2. $\Sigma + \mathcal{M}$: deactivate safe mode *and* reverse epigenetic methylation

Both pairs combine an energy-producing restoration with the removal of the epigenetic lock. The model produces a key clinical prediction: for severe ME/CFS, even aggressive mitochondrial or immune therapy will fail unless accompanied by epigenetic intervention (e.g., HDAC inhibitors, demethylating agents, or sustained interventions long enough for natural epigenetic reversal).

~ Hypothesis 1: Minimum Lock Release Theorem

For the severe/locked ME/CFS attractor, no single-parameter restoration is sufficient for recovery. The minimum intervention set requires *at least two* simultaneous restorations: one targeting an energy-producing mechanism (α_{CI} or Σ) and one targeting epigenetic consolidation ($\mathcal{M}$). This predicts that:

1. Single-target therapies (e.g., CoQ10 alone, LDN alone, immunoadsorption alone) will produce at most partial improvement in severe ME/CFS; the model predicts that full recovery requires multi-target intervention.
2. Combination therapies pairing mitochondrial support with epigenetic modifiers will show qualitatively different (not merely additive) outcomes compared to either alone.
3. The duration of illness before treatment initiation is a critical predictor of treatment response, because longer duration implies deeper epigenetic consolidation and higher $\mathcal{M}$.
4. Early intervention (before full epigenetic consolidation, estimated at < 2 years post-onset based on τ_{epi} from Equation 39.24) may achieve recovery with single-target therapy, while late intervention requires combination therapy.

Certainty: 0.40. The requirement for multi-target intervention in the severe attractor is a robust consequence of the positive feedback structure and epigenetic hysteresis, but

the specific parameter combinations and thresholds depend on model details not yet validated against patient data. The prediction that early intervention is more effective is consistent with clinical observations but has not been tested in controlled trials with the specific combination therapies predicted by this model.

42.6.3 Interpretation: Why Epigenetic Reversal Is Rate-Limiting

The prominence of $\mathcal{M}$ in the minimum intervention sets has a clear dynamical explanation. Consider the epigenetic modulation of Complex I (Equation 39.21):

$$\alpha_{\text{CI}}(\mathcal{E}) = \alpha_{\text{CI},0} \cdot (1 - \epsilon_{\text{CI}} \cdot \mathcal{M}) \quad (42.35)$$

In the severe attractor, $\mathcal{M}$ has consolidated to a high value ($\mathcal{M} \approx 0.7\text{--}0.8$). Even if an intervention restores the intrinsic Complex I parameter $\alpha_{\text{CI},0}$ to its healthy value, the *effective* Complex I activity remains suppressed by the epigenetic factor $(1 - \epsilon_{\text{CI}} \cdot \mathcal{M})$. With $\epsilon_{\text{CI}} \approx 0.3$ and $\mathcal{M} \approx 0.75$:

$$\alpha_{\text{CI}}^{\text{eff}} = 1.0 \cdot (1 - 0.3 \times 0.75) = 0.775 \quad (42.36)$$

This effective value is above the critical threshold (0.65), but only barely—and the analogous epigenetic suppression of immune exhaustion (k_{exh}) and mitochondrial biogenesis ($J_{\text{biogenesis}}$) collectively keep the system within $\mathcal{B}_d$. Reversing $\mathcal{M}$ removes this epigenetic brake, allowing the intrinsic parameter restoration to take full effect.

42.7 Treatment Priority Derivation

The results of Sections E.4–42.6 can be synthesized into a formal treatment priority ranking for each disease subtype.

42.7.1 Priority Score Definition

For each parameter θ_j and disease subtype s , define a composite treatment priority score:

$$\mathcal{P}_{j,s} = w_N \cdot N_{j,s} + w_S \cdot S_j^T + w_\tau \cdot \frac{1}{\tau_j} \quad (42.37)$$

where:

- $N_{j,s} \in \{0, 1\}$: lock necessity indicator (1 if restoring θ_j alone achieves escape from subtype s ; 0 otherwise)
- S_j^T : total-effect Sobol index (Table 42.7), representing influence on disease state

- τ_j : timescale of response to θ_j restoration (faster response = higher priority)
- w_N, w_S, w_τ : weighting coefficients with $w_N > w_S > w_\tau$ (lock-breaking dominates sensitivity, which dominates speed)

With $w_N = 5.0, w_S = 2.0, w_\tau = 1.0$, and response timescales estimated from the ODE dynamics. The specific ratio 5:2:1 reflects the qualitative ordering $w_N > w_S > w_\tau$ (lock-breaking capacity dominates sensitivity, which dominates therapeutic speed). Sensitivity of the priority rankings to these weight choices has not been formally assessed; the rankings should be interpreted as indicative rather than definitive.

42.7.2 Treatment Priority Tables

Table 42.16: Treatment priority ranking for each ME/CFS subtype. Higher $\mathcal{P}_{j,s}$ = higher priority. Intervention column maps parameters to available therapies.

Immune-dominant subtype			
Rank	Target parameter	$\mathcal{P}_{j,s}$	Candidate intervention
1	k_{exh} (immune exh.)	6.62	Immune checkpoint modulation, LDN
2	α_{CI} (Complex I)	1.84	CoQ10, NAD ⁺ precursors
3	Σ (safe mode)	1.56	Anti-inflammatory to reduce $\mathcal{T}$
4	[AAb] (autoantibodies)	1.38	Immunoadsorption, rituximab
Metabolic-dominant subtype			
1	α_{CI} (Complex I)	6.84	CoQ10, d-ribose, NAD ⁺ precursors
2	Σ (safe mode)	6.56	Reduce threat signal, anti-inflammatory
3	k_{exh} (immune exh.)	1.62	LDN
4	$\mathcal{M}$ (methylation)	1.44	SAMe modulation, time
Neurovascular-dominant subtype			
1	[AAb] (autoantibodies)	6.38	Immunoadsorption, rituximab
2	α_{CI} (Complex I)	1.84	CoQ10, NAD ⁺ precursors
3	k_{exh} (immune exh.)	1.62	LDN
4	Σ (safe mode)	1.56	Anti-inflammatory
Severe/locked subtype (requires combination)			
1	$\mathcal{M}$ (methylation)	2.18 [†]	Epigenetic modulators, sustained intervention
2	α_{CI} (Complex I)	1.84	CoQ10, NAD ⁺ precursors
3	Σ (safe mode)	1.56	Anti-inflammatory
4	k_{exh} (immune exh.)	1.62	LDN

[†] No single parameter achieves escape; $\mathcal{M}$ ranks first because it is required in all successful pairs.

The priority tables encode a fundamental asymmetry: for the three milder subtypes, the first-priority intervention targets the subtype's defining lock and is predicted to be sufficient alone. For the severe subtype, the first-priority intervention (epigenetic reversal) is *necessary but insufficient*—it must be combined with an energy-producing restoration (rank 2 or 3).

42.7.3 Response Timescale Estimates

The priority score incorporates response timescale τ_j , estimated from the characteristic timescales of each ODE subsystem:

Table 42.17: Estimated response timescales for parameter restorations, derived from eigenvalue analysis of the relevant subsystem Jacobians.

Parameter	Subsystem	τ_j (estimated)	Limiting process
α_{CI}	Energy metabolism	1–3 days	ATP turnover, ETC equilibration
k_{exh}	Immune regulation	2–6 weeks	T cell dynamics, exhaustion reversal
Σ	Safe mode switch	1–4 weeks	Hysteresis crossing time
[AAb]	Autoantibody	3–6 months	IgG clearance ($t_{1/2} \approx 21$ days), plasma cell depletion
$\mathcal{M}$	Epigenetic	6–24 months	Passive demethylation, cell turnover
g_{TRPM3}	Calcium signaling	hours–days	Channel expression, membrane turnover

The timescale hierarchy spans four orders of magnitude, from hours (calcium signaling) to years (epigenetic reversal). This has a critical implication for clinical trial design: short trials (< 3 months) can only detect responses mediated by fast-responding parameters (α_{CI} , g_{TRPM3} , Σ), while trials targeting autoantibody clearance or epigenetic reversal require observation periods of ≥ 6 months and ≥ 18 months, respectively. The high failure rate of ME/CFS clinical trials may partly reflect this mismatch between intervention timescale and observation period.

42.7.4 Relationship to Existing Treatment Evidence

The model-derived priority rankings can be compared with existing clinical evidence:

- **CoQ10/NAD⁺ precursors** (targeting α_{CI}): ranked 1st for the metabolic subtype. Clinical evidence shows modest but consistent benefit in open-label studies [621], with effect sizes consistent with the model's prediction of improvement without subtype stratification (response diluted by non-metabolic patients).
- **LDN** (targeting k_{exh} via microglial modulation): ranked 1st for the immune subtype. Open-label studies show 30–50% response rates in unselected ME/CFS populations [595, 159]—consistent with the ~30% prevalence of immune-dominant patients if the model's subtype distribution is approximately correct.
- **Rituximab** (targeting [AAb] via B cell depletion): initially showed promise in open-label trials but failed in the RituxME RCT [505]. The model predicts rituximab would succeed only in the neurovascular-dominant subtype (~20% of patients), consistent with the RCT's null result in an unselected population.
- **No single therapy for severe ME/CFS**: the model's prediction that severe patients require combination therapy is consistent with the clinical observation that no monotherapy has demonstrated efficacy in severe, long-duration ME/CFS [505].

These post-hoc consistencies do not validate the model but demonstrate that its predictions are not contradicted by available evidence. Prospective validation requires subtype-stratified trials (Section 42.8).

42.8 Predictions and Falsification

The formal causal hierarchy analysis generates four specific, testable predictions. Each includes explicit falsification criteria.

42.8.1 Prediction 1: Subtype-Specific Lock Breaking

Prediction. Treatment response is determined by the match between the intervention target and the patient's dominant attractor. Specifically:

- Immune-modulating therapies (e.g., rituximab, LDN) will show $\geq 50\%$ response rate in the immune-dominant subtype and $\leq 15\%$ in the metabolic-dominant subtype.
- Mitochondrial support (e.g., high-dose CoQ10 + NAD⁺ precursors) will show $\geq 50\%$ response rate in the metabolic-dominant subtype and $\leq 15\%$ in the immune-dominant subtype.
- Immunoadsorption will show $\geq 50\%$ response rate in the neurovascular-dominant subtype and $\leq 20\%$ in the metabolic-dominant subtype.

Falsification. This prediction is falsified if a treatment targeting the “wrong” subtype (e.g., CoQ10 alone for immune-dominant patients) shows a response rate $> 30\%$, indicating that the subtype classification does not determine treatment response.

Required data. Multi-omics subtyping (to classify patients into attractors) combined with randomized treatment assignment.

42.8.2 Prediction 2: Severe Subtype Requires Combination Therapy

Prediction. Single-target therapies will show $< 20\%$ sustained improvement in severe/locked ME/CFS (illness duration > 5 years, all subsystems degraded), while combination therapy targeting energy production + epigenetic modulation will show $\geq 40\%$ sustained improvement.

Falsification. This prediction is falsified if a single-target therapy achieves $> 30\%$ sustained (> 6 months) improvement in the severe subtype, indicating that multi-target intervention is not necessary.

Required data. Controlled comparison of single vs. combination therapy in patients stratified by severity and duration.

42.8.3 Prediction 3: Early Intervention Window

Prediction. The response rate to any given therapy declines with illness duration, with a critical transition at approximately $\tau_{\text{epi}} \approx 18\text{--}24$ months post-onset (the timescale for epigenetic consolidation, estimated from Equation 39.24). Patients treated within this window will show 2–3 $\times$ higher response rates than patients treated after the window.

Falsification. This prediction is falsified if treatment response is independent of illness duration (no significant difference in response rates before vs. after the 24-month mark), or if the transition occurs at a substantially different timescale (< 6 months or > 5 years), indicating that the epigenetic consolidation model is incorrect.

Required data. Treatment trials stratified by illness duration with sufficient sample size to detect duration-dependent response differences.

Quantitative formalization. The epigenetic consolidation model (Equation 39.24) predicts an exponential approach to the consolidated state:

$$\mathcal{M}(t) = \mathcal{M}_d^* \cdot (1 - e^{-t/\tau_{\text{epi}}}) \quad (42.38)$$

where $\mathcal{M}_d^*$ is the fully consolidated methylation index and $\tau_{\text{epi}} = 1/(k_{\text{DNMT}} \cdot C_{\text{pro}}^* + k_{\text{demeth}})$ is the consolidation timescale. The treatment response probability $p_{\text{response}}(t)$ for a given therapy is predicted to follow:

$$p_{\text{response}}(t) = p_0 \cdot \frac{K_{\mathcal{M}}}{K_{\mathcal{M}} + \mathcal{M}(t)} = p_0 \cdot \frac{K_{\mathcal{M}}}{K_{\mathcal{M}} + \mathcal{M}_d^* \cdot (1 - e^{-t/\tau_{\text{epi}}})} \quad (42.39)$$

where p_0 is the response probability at disease onset ($\mathcal{M} = 0$) and $K_{\mathcal{M}}$ is the half-inhibition constant for epigenetic-mediated treatment resistance. This predicts a sigmoidal decline in treatment efficacy, with the steepest decline at $t \approx \tau_{\text{epi}}$.

42.8.4 Prediction 4: Critical Slowing Down Before Relapse

Prediction. Patients approaching the separatrix Σ_{sep} (whether improving toward health or worsening toward a deeper attractor) will exhibit critical slowing down: increased autocorrelation and variance in symptom and biomarker time series. This is a generic property of systems near bifurcation points (Chapter 40).

Specifically, the model predicts that a sustained increase of $> 2\sigma$ in the 7-day rolling variance of heart rate variability, combined with increased autocorrelation at lag 1 ($r_1 > 0.7$), precedes attractor transitions by 2–4 weeks.

Mathematical basis. Near a saddle-node bifurcation, the dominant eigenvalue λ_1 of the Jacobian approaches zero. The autocorrelation at lag Δt for a linearized stochastic system is:

$$\rho(\Delta t) = e^{\lambda_1 \cdot \Delta t} \quad (42.40)$$

As $\lambda_1 \rightarrow 0^-$ (approaching the bifurcation), $\rho(\Delta t) \rightarrow 1$ for any finite Δt —the system “remembers” perturbations for longer. Simultaneously, the variance of fluctuations scales as $\sigma^2 \propto 1/|\lambda_1|$, diverging at the bifurcation. These two signatures—rising autocorrelation and rising variance—are the hallmarks of critical slowing down.

In the 67-variable ME/CFS model, the relevant eigenvalue λ_1 is the one associated with the energy-immune feedback loop (the slowest unstable direction near the separatrix). Projecting the dynamics onto an observable (e.g., heart rate, which integrates autonomic, metabolic, and immune state), the critical slowing down signal is expected to be detectable provided the noise-to-signal ratio is not too large and the observation timescale is shorter than $1/|\lambda_1|$.

Falsification. This prediction is falsified if attractor transitions (sustained improvement or sustained worsening) are not preceded by detectable changes in variance and autocorrelation, indicating that the transitions are either too abrupt for early warning, the observable (HRV) does not project onto the critical mode, or stochastic driving overwhelms the deterministic slowing down signal.

Required data. Continuous physiological monitoring (wearable HRV, activity tracking) in a cohort of ME/CFS patients over ≥ 12 months, with concurrent symptom and biomarker assessments. Statistical power analysis suggests $n \geq 50$ patients with at least 5 detected transitions (improvement or worsening) are needed to test for the autocorrelation signature at $\alpha = 0.05$.

? Open Question 1: Identifiability of Separatrix Proximity

Can the distance of a patient’s current state from the separatrix Σ_{sep} be estimated from clinically measurable biomarkers? The separatrix in the full 67-dimensional state space is a 66-dimensional hypersurface; projecting the patient’s state onto the normal direction of Σ_{sep} would yield a scalar “recovery distance” metric. Computing this metric requires: (1) a patient-specific parameter estimate $\hat{\theta}_{\text{patient}}$ (from biomarker fitting, Section 41.2.1); (2) numerical computation of Σ_{sep} for that parameter set; and (3) projection of the current state estimate onto the separatrix normal. If feasible, this metric would enable quantitative treatment response monitoring—not merely “is the patient improving?” but “how close is the patient to the tipping point for recovery?”

42.9 Conclusion

This chapter has transformed the qualitative causal hierarchy proposed in Chapter 16 into a quantitative framework grounded in the 67-variable ODE model. The three formal tools—trigger sufficiency, parameter sensitivity, and lock removal—provide complementary perspectives on the same question: what causes ME/CFS, what maintains it, and what would it take to reverse it?

The principal findings are:

1. **Three trigger-sufficient mechanisms:** Complex I reduction, metabolic safe mode activation, and GPCR autoantibodies can each independently initiate ME/CFS. TRPM3

dysfunction is a strong predisposing factor but not independently trigger-sufficient. Different triggering mechanisms may lead to different disease subtypes, consistent with the multi-attractor structure (Section 39.8).

2. **Subtype-specific necessary locks:** Each of the three milder subtypes (immune-dominant, metabolic-dominant, neurovascular-dominant) has a specific necessary lock whose removal is sufficient for recovery: immune exhaustion, energy production, and autoantibody clearance, respectively. This provides a rational basis for treatment stratification (Chapter 41).
3. **Severe attractor requires combination therapy:** No single-parameter restoration rescues the severe/locked attractor. The minimum intervention set requires two simultaneous restorations, one of which must target epigenetic consolidation. This explains the clinical observation that severe, long-duration ME/CFS is resistant to single-target therapies.
4. **Epigenetic consolidation as a master lock:** Epigenetic methylation appears in all successful intervention sets for the severe attractor and modulates the effectiveness of other interventions at all severity levels. This places epigenetic dynamics—operating on timescales of months to years—at the center of disease persistence and treatment resistance.

All quantitative results in this chapter are derived from analytical properties of reduced subsystem models. Full numerical simulation of the 67-variable system is required to confirm the thresholds, interaction coefficients, and minimum intervention sets reported here.

These results bridge the qualitative insights of Chapter 16 (Sections 16.1–16.6) and the quantitative models of Chapters 36–39, creating a unified framework that generates testable predictions (Section 42.8) and actionable treatment priorities (Section 42.7).

Correspondence with the Qualitative Hierarchy

Table 42.18 maps the qualitative categories of Chapter 16 to the formal results of this chapter:

Table 42.18: Mapping between the qualitative causal hierarchy (Chapter 16) and the formal analysis of this chapter. Each qualitative category receives a precise mathematical definition and quantitative criteria.

Qualitative category	Formal definition	Key result
Trigger-capable root cause	Trigger-sufficient (Def. 42.1)	Complex I, safe mode, autoantibodies verified; TRPM3 conditional
Amplifier	$S_j^T > 0.05$, not trigger-sufficient, not a necessary lock	TRPM3, epigenetic state, gut permeability, microclots, sensitization
Load-bearing lock	Lock-necessary (Def. 42.2)	Subtype-specific: k_{exh} (immune), $\alpha_{\text{CI}}/\Sigma$ (metabolic), [AAb] (neurovascular)

The formal analysis both confirms and refines the qualitative classification. The major refinement is the identification of *subtype dependence*: a mechanism's role in the causal hierarchy depends on which disease attractor the patient occupies. Complex I reduction is a trigger and a lock for the metabolic subtype but merely an amplifier for the immune-dominant subtype. This context-dependent classification is invisible to qualitative reasoning but emerges naturally from the mathematical structure of the coupled ODE system.

Limitations and Next Steps

The analyses in this chapter rest on several assumptions that must be tested:

1. **Reduced model validity:** Trigger thresholds and lock removal outcomes were derived from reduced subsystem models, not the full 67-variable system. Emergent behaviors arising from the coupling of all subsystems may shift thresholds or change qualitative outcomes. Numerical simulation of the full system with realistic parameter ranges is the essential next step.
2. **Parameter uncertainty:** Many model parameters (Tables 42.1–42.3) are estimated rather than measured. The qualitative predictions (which mechanisms are triggers, locks, or amplifiers) are expected to be robust to moderate parameter uncertainty, but the quantitative thresholds may shift substantially. Bayesian uncertainty propagation through the full model would quantify this robustness.
3. **Discrete patient subtyping:** The model predicts discrete attractors, but real patients may occupy intermediate positions (near separatrices, transitioning between attractors, or in mixed states). The sharpness of the subtype boundaries in practice is an empirical question addressable through multi-omics clustering studies.
4. **Treatment as parameter restoration:** The priority score (Equation 42.37) assumes that treatments act by restoring disease parameters toward healthy values. In practice, treatments have off-target effects, pharmacokinetic variability, and dose–response nonlinearities not captured in the current analysis. Integration with the pharmacokinetic–pharmacodynamic framework of Chapter 41 (Section 41.2.2) would improve clinical relevance.
5. **Temporal sequencing of interventions:** The minimum intervention set analysis (Section 42.6) identifies *which* parameters must be restored simultaneously but does not address *temporal ordering*. In practice, some interventions must precede others (e.g., reducing inflammation before attempting epigenetic reversal). Optimal temporal sequencing requires dynamic optimization over the ODE trajectories, an extension left for future work.

The critical next step is numerical validation of the full 67-variable system, which will either confirm the qualitative predictions derived here from reduced models or reveal emergent behaviors not captured by subsystem analysis. Chapter 41 translates these findings into clinical decision support tools; the formal hierarchy analysis provides the mechanistic foundation that those tools require.

A Glossary of Medical and Scientific Terms

This glossary defines medical, biochemical, immunological, and statistical terms used throughout this document. Terms are organized alphabetically. Where a term is used in a specialized sense specific to ME/CFS research, the ME/CFS-specific usage is indicated.

A

Acetyl-CoA Acetyl coenzyme A; the two-carbon unit that enters the Krebs cycle, produced from pyruvate (via pyruvate dehydrogenase), fatty acids (via β -oxidation), or amino acids.

ACTH Adrenocorticotrophic hormone; pituitary hormone that stimulates cortisol production by the adrenal cortex. Part of the HPA axis.

Adenosine triphosphate (ATP) The primary intracellular energy currency. Hydrolysis of ATP to ADP releases energy for cellular processes.

Aerobic glycolysis Glycolysis occurring in the presence of oxygen, with pyruvate entering the Krebs cycle rather than being converted to lactate. Distinct from anaerobic glycolysis.

Allostatic load The cumulative physiological cost of chronic stress and adaptation. In ME/CFS, elevated allostatic load reflects multi-system dysregulation.

AMP-activated protein kinase (AMPK) A cellular energy sensor activated by high AM-P/ATP ratios. Triggers catabolic pathways to restore energy balance.

Anaerobic threshold (AT) The exercise intensity above which lactate production exceeds clearance, causing blood lactate to rise. Reduced in ME/CFS.

Autoantibody An antibody directed against the body's own proteins. Autoantibodies against adrenergic and muscarinic receptors have been identified in ME/CFS subsets.

Autonomic nervous system (ANS) The division of the nervous system controlling involuntary functions (heart rate, blood pressure, digestion) through sympathetic and parasympathetic branches.

B

Baroreflex The reflex arc that maintains blood pressure by adjusting heart rate and vascular tone in response to changes detected by arterial baroreceptors.

Bell Disability Scale A 0–100 rating scale for functional capacity in ME/CFS, where 100 represents normal function and 0 represents bedridden and dependent.

Bistability A dynamical system property in which two stable steady states coexist for the same parameter values. Transition between states requires a perturbation exceeding a threshold.

Blood–brain barrier (BBB) The selective permeability barrier formed by endothelial cells of cerebral capillaries, restricting passage of molecules and immune cells into the CNS.

Butyrate A short-chain fatty acid produced by gut bacteria from dietary fiber. Maintains intestinal barrier integrity and exerts anti-inflammatory effects.

C

Cardiopulmonary exercise testing (CPET) A diagnostic test measuring oxygen consumption, carbon dioxide production, and ventilation during graded exercise. The two-day CPET protocol is used to objectively demonstrate PEM.

Cell danger response (CDR) A conserved metabolic response to cellular threat, characterized by reduced mitochondrial function and extracellular ATP/ADP signaling. Proposed as a unifying mechanism in ME/CFS by Naviaux.

Central sensitization Enhanced responsiveness of central nervous system neurons to input, resulting in amplified pain and sensory perception.

Cholinergic anti-inflammatory pathway A neuroimmune reflex in which vagal efferent signals suppress macrophage TNF- α production through $\alpha 7$ nicotinic acetylcholine receptors.

Circadian rhythm Endogenous biological oscillations with approximately 24-hour periodicity, governed by the suprachiasmatic nucleus and peripheral clock genes.

Coenzyme Q10 (CoQ10) Ubiquinone; an electron carrier in the mitochondrial electron transport chain between Complexes I/II and Complex III. Also functions as a lipid-soluble antioxidant.

Corticotropin-releasing hormone (CRH) Hypothalamic hormone that initiates the HPA axis cascade by stimulating pituitary ACTH release.

Cortisol The primary glucocorticoid hormone produced by the adrenal cortex. Regulates metabolism, immune function, and stress response. Mildly reduced in ME/CFS.

Cytokine A small signaling protein secreted by immune cells that mediates and regulates immunity, inflammation, and hematopoiesis. Key examples: IL-1 β , IL-6, TNF- α , IFN- γ , IL-10.

D–E

DePaul Symptom Questionnaire (DSQ) A validated self-report instrument for assessing ME/CFS symptom frequency and severity across multiple domains.

Digital twin A patient-specific computational model continuously updated with real-time data to predict individual disease trajectory and treatment response.

Dysautonomia Dysfunction of the autonomic nervous system. In ME/CFS, manifests as orthostatic intolerance, POTS, temperature dysregulation, and gastrointestinal dysmotility.

Electron transport chain (ETC) The series of protein complexes (I–IV) in the inner mitochondrial membrane that transfer electrons from NADH/FADH₂ to oxygen, generating the proton gradient that drives ATP synthesis.

Energy envelope The maximum amount of energy a patient can expend without triggering post-exertional malaise. Concept formalized by Jason et al.

Epigenetics Heritable changes in gene expression that do not involve changes to the DNA sequence. Includes DNA methylation, histone modification, and non-coding RNA regulation. Epigenetic alterations have been documented in ME/CFS.

F–G

Fibromyalgia (FM) A chronic pain condition frequently comorbid with ME/CFS, characterized by widespread musculoskeletal pain and tenderness.

Fukuda criteria A 1994 case definition for CFS requiring ≥ 6 months of unexplained fatigue plus ≥ 4 of 8 specified symptoms. Less specific than the ICC or CCC criteria.

Glymphatic system The brain's waste clearance system, dependent on aquaporin-4 water channels and active primarily during sleep. Impaired glymphatic function may contribute to unrefreshing sleep and cognitive dysfunction.

Graded exercise therapy (GET) A structured exercise program involving progressive increases in physical activity. Contraindicated in ME/CFS per NICE 2021 guidelines due to risk of harm.

Gut–brain axis The bidirectional communication system between the gastrointestinal tract and the central nervous system, involving neural (vagal), immune, endocrine, and microbial signaling pathways.

H–I

Heart rate variability (HRV) The variation in time intervals between consecutive heartbeats. Reduced HRV indicates autonomic dysfunction, particularly reduced parasympathetic tone. Consistently abnormal in ME/CFS.

Hill function A mathematical function describing cooperative binding or sigmoidal dose–response relationships: $f(x) = x^n / (K^n + x^n)$, where n is the Hill coefficient and K is the half-saturation constant.

HPA axis Hypothalamic–pituitary–adrenal axis; the neuroendocrine cascade (CRH $\rightarrow$ ACTH $\rightarrow$ cortisol) that regulates the stress response and cortisol production.

Hypometabolism A state of reduced metabolic activity. In ME/CFS, refers to the systemic downregulation of metabolic pathways documented by metabolomics studies.

IDO (Indoleamine 2,3-dioxygenase) An enzyme that converts tryptophan to kynurenine. Upregulated by IFN- γ , diverting tryptophan away from serotonin synthesis.

Immune exhaustion Progressive loss of effector function in T cells or NK cells due to chronic antigen stimulation. Characterized by upregulation of inhibitory receptors (PD-1, Tim-3, LAG-3).

International Consensus Criteria (ICC) A 2011 case definition for ME requiring post-exertional neuroimmune exhaustion plus neurological, immune, and energy metabolism symptoms. More specific than the Fukuda criteria.

K–M

Krebs cycle (Also: citric acid cycle, tricarboxylic acid cycle.) The metabolic pathway in the mitochondrial matrix that oxidizes acetyl-CoA to CO₂, generating NADH, FADH₂, and GTP.

Kynurenine pathway The metabolic pathway converting tryptophan to nicotinamide (NAD⁺ precursor) via kynurenine, 3-hydroxykynurenine, and quinolinic acid. Produces both neuroprotective and neurotoxic metabolites.

Lipopolysaccharide (LPS) A component of gram-negative bacterial cell walls. A potent activator of innate immunity through TLR4 signaling. Elevated circulating LPS (endotoxemia) may result from intestinal barrier dysfunction in ME/CFS.

Low-dose naltrexone (LDN) An opioid receptor antagonist used at sub-therapeutic doses (1–5 mg) for immunomodulatory effects. Investigated as an off-label treatment for ME/CFS.

Mast cell activation syndrome (MCAS) A condition characterized by excessive mast cell mediator release, producing symptoms overlapping with ME/CFS (fatigue, brain fog, flushing, gastrointestinal disturbance).

Metabolic trap A hypothesis proposing that ME/CFS involves a stable biochemical state in which a metabolic pathway remains locked in a dysfunctional configuration due to bistability in enzyme kinetics.

Michaelis–Menten kinetics A model of enzyme-catalyzed reaction rates: $v = V_{\max}[S]/(K_m + [S])$, where $V_{\max}$ is the maximal rate and K_m is the substrate concentration at half-maximal rate.

Microglia The resident immune cells of the central nervous system. Activated microglia produce neuroinflammatory mediators implicated in cognitive dysfunction and central sensitization.

Mitochondria Double-membrane organelles responsible for aerobic ATP production via the Krebs cycle and electron transport chain. Mitochondrial dysfunction is a central feature of ME/CFS pathophysiology.

N–O

NAD⁺ /NADH Nicotinamide adenine dinucleotide (oxidized/reduced forms). Essential electron carriers in cellular metabolism. The NAD⁺ /NADH ratio reflects cellular redox state and regulates metabolic flux.

Natural killer (NK) cells Innate immune lymphocytes that kill virally infected and transformed cells. Reduced NK cell cytotoxicity is one of the most replicated immunological findings in ME/CFS.

Neuroinflammation Inflammation within the central nervous system, mediated primarily by activated microglia and astrocytes. PET imaging has demonstrated neuroinflammation in ME/CFS patients.

Orthostatic intolerance (OI) Inability to tolerate upright posture, with symptoms (light-headedness, palpitations, nausea, pre-syncope) that improve with recumbency. Affects the majority of ME/CFS patients.

Oxidative phosphorylation (OXPHOS) The process by which ATP is synthesized using energy from the mitochondrial proton gradient generated by the electron transport chain.

Oxidative stress An imbalance between reactive oxygen species production and antioxidant defense, resulting in cellular damage to lipids, proteins, and DNA.

P–R

Pacing An activity management strategy in which patients maintain energy expenditure within their energy envelope to prevent post-exertional malaise.

Post-exertional malaise (PEM) The hallmark symptom of ME/CFS: a disproportionate worsening of symptoms following physical, cognitive, or emotional exertion, typically delayed by 12–72 hours and lasting days to weeks.

Postural orthostatic tachycardia syndrome (POTS) A form of orthostatic intolerance defined by a sustained heart rate increase ≥ 30 bpm within 10 minutes of standing, without orthostatic hypotension.

Proton-motive force The electrochemical gradient across the inner mitochondrial membrane, composed of the membrane potential ($\Delta\Psi$) and the pH gradient (ΔpH). Drives ATP synthesis by Complex V.

Reactive oxygen species (ROS) Chemically reactive molecules derived from molecular oxygen, including superoxide ($\text{O}_2^{\bullet-}$), hydrogen peroxide (H_2O_2), and hydroxyl radical ($\bullet\text{OH}$). Generated as byproducts of mitochondrial electron transport.

Rituximab A monoclonal antibody targeting CD20 on B cells, causing B cell depletion. Investigated for ME/CFS based on an autoimmune hypothesis; phase III trial did not demonstrate efficacy.

S–T

Sensitivity analysis A mathematical technique for determining which model parameters most strongly influence model outputs. Global sensitivity analysis (Sobol indices) partitions output variance across parameters and interactions.

Separatrix In dynamical systems theory, the boundary between basins of attraction. In the ME/CFS bistability model, the separatrix divides state space into regions that converge to the healthy state versus the disease state.

SF-36 (Short Form Health Survey) A 36-item questionnaire measuring eight domains of health-related quality of life. ME/CFS patients score lower than patients with most other chronic conditions.

Short-chain fatty acids (SCFAs) Fatty acids with fewer than 6 carbon atoms (acetate, propionate, butyrate) produced by bacterial fermentation of dietary fiber in the colon.

Sickness behavior A coordinated set of behavioral changes (fatigue, social withdrawal, anorexia, hyperalgesia) triggered by pro-inflammatory cytokines acting on the brain. Proposed as a model for ME/CFS symptomatology.

Sympathetic nervous system (SNS) The division of the autonomic nervous system responsible for “fight-or-flight” responses: increased heart rate, blood pressure, bronchodilation, and metabolic rate.

Tilt table testing A diagnostic procedure for orthostatic intolerance in which the patient is passively tilted from supine to upright while heart rate and blood pressure are monitored.

Tryptophan An essential amino acid and precursor for serotonin synthesis (via tryptophan hydroxylase) and kynurenine production (via IDO). Competition between these pathways is relevant to ME/CFS.

U–Z

Ubiquinone See Coenzyme Q10.

Vagus nerve The tenth cranial nerve; the primary parasympathetic nerve providing afferent and efferent innervation to thoracic and abdominal organs. Mediates the cholinergic anti-inflammatory pathway.

Warburg effect The metabolic shift from oxidative phosphorylation to aerobic glycolysis, originally described in cancer cells but also characteristic of activated immune cells.

B List of Abbreviations

ACTH	Adrenocorticotrophic hormone
ADP	Adenosine diphosphate
ANS	Autonomic nervous system
ATP	Adenosine triphosphate
BBB	Blood-brain barrier
CBC	Complete blood count
CDC	Centers for Disease Control and Prevention
CFS	Chronic fatigue syndrome
CMV	Cytomegalovirus
CNS	Central nervous system
CoQ10	Coenzyme Q10
CPET	Cardiopulmonary exercise testing
CRH	Corticotropin-releasing hormone
CSF	Cerebrospinal fluid
DHA	Docosahexaenoic acid
EBV	Epstein-Barr virus
EPA	Eicosapentaenoic acid
ETC	Electron transport chain
FMT	Fecal microbiota transplantation
GABA	Gamma-aminobutyric acid
GET	Graded exercise therapy
GWAS	Genome-wide association study
HHV-6	Human herpesvirus 6
HPA	Hypothalamic-pituitary-adrenal
HRV	Heart rate variability
IBS	Irritable bowel syndrome
ICC	International Consensus Criteria
ICD	International Classification of Diseases
IgG/IgM	Immunoglobulin G/M
IL	Interleukin
IOM	Institute of Medicine
IVIG	Intravenous immunoglobulin
LDN	Low-dose naltrexone
LPS	Lipopolysaccharide

MCAS	Mast cell activation syndrome
MCT	Medium-chain triglycerides
ME	Myalgic encephalomyelitis
ME/CFS	Myalgic encephalomyelitis/chronic fatigue syndrome
MRI	Magnetic resonance imaging
NAC	N-acetylcysteine
NAD⁺/NADH	Nicotinamide adenine dinucleotide (oxidized/reduced)
NK	Natural killer (cells)
NSAID	Non-steroidal anti-inflammatory drug
ODE	Ordinary differential equation
PBMC	Peripheral blood mononuclear cell
PDE	Partial differential equation
PEM	Post-exertional malaise
PENE	Post-exertional neuroimmune exhaustion
PESE	Post-exertional symptom exacerbation
PET	Positron emission tomography
POTS	Postural orthostatic tachycardia syndrome
RCT	Randomized controlled trial
ROS	Reactive oxygen species
SEID	Systemic exertion intolerance disease
SIBO	Small intestinal bacterial overgrowth
SNP	Single nucleotide polymorphism
SPECT	Single-photon emission computed tomography
TCA	Tricarboxylic acid (Krebs cycle)
TENS	Transcutaneous electrical nerve stimulation
TGF-β	Transforming growth factor beta
TNF-α	Tumor necrosis factor alpha
Treg	Regulatory T cell
WHO	World Health Organization

C Diagnostic Tools and Assessment Scales

This appendix describes the principal diagnostic instruments and assessment tools used in ME/CFS clinical evaluation and research. For each tool, we specify its purpose, administration procedure, scoring, interpretation, and known limitations in ME/CFS populations.

C.1 Symptom Questionnaires

C.1.1 DePaul Symptom Questionnaire (DSQ)

The DePaul Symptom Questionnaire is a validated self-report instrument developed specifically for ME/CFS research and clinical assessment [793].

Purpose Systematic assessment of ME/CFS symptom frequency and severity across multiple domains; enables classification according to multiple case definitions (Fukuda, CCC, ICC).

Administration Self-administered paper or electronic questionnaire; approximately 20–30 minutes to complete.

Content 54 symptom items, each rated on two scales: frequency (0 = none of the time, 4 = all of the time) and severity (0 = symptom absent, 4 = very severe). Additional items capture demographics, illness onset, and functional status.

Scoring Composite domain scores are calculated for fatigue, post-exertional malaise, sleep dysfunction, pain, neurocognitive symptoms, autonomic dysfunction, neuroendocrine symptoms, and immune symptoms. A symptom is considered clinically significant when frequency ≥ 2 and severity ≥ 2 .

Interpretation The DSQ enables operationalized application of diagnostic criteria. For the ICC, PEM must score ≥ 2 on both frequency and severity, plus at least one symptom in each required category (neurological, immune, energy metabolism).

Strengths Validated psychometric properties; enables systematic case identification; widely used in ME/CFS research, facilitating cross-study comparison.

Limitations Self-report introduces subjective variability; cognitively impaired patients may require assistance; does not capture symptom timing or PEM delay characteristics.

C.1.2 Bell Disability Scale

The Bell Disability Scale provides a single-number rating of functional capacity [177].

Purpose Rapid assessment of overall functional impairment; tracking disease severity over time.

Administration Clinician-rated or self-rated; takes less than 5 minutes.

Scoring A single score from 0 to 100 in increments of 10:

- **100:** Normal activity, no symptoms
- **80:** Normal activity with effort, mild symptoms
- **60:** Can work part-time with rest periods; moderate symptoms
- **50:** Can perform light duties with rest; unable to work full-time
- **40:** Mostly homebound; severe symptoms with activity
- **30:** Mostly bedridden; severe symptoms at rest
- **20:** Bedridden most of the day; unable to perform self-care independently
- **10:** Bedridden and dependent; severe symptoms continuously
- **0:** Bedridden, unable to sit up; critically ill

Interpretation Scores correspond approximately to NICE 2021 severity grades [254]: Mild (≥ 60), Moderate (40–50), Severe (20–30), Very Severe (≤ 10).

Strengths Quick to administer; provides a standardized severity metric; sensitive to change over time.

Limitations Coarse granularity (10-point increments); does not capture symptom domains; subjective calibration varies between raters.

C.2 Functional Assessments

C.2.1 SF-36 (Short Form Health Survey)

The SF-36 is a generic health-related quality of life instrument widely used across chronic diseases, providing a benchmark for comparing ME/CFS functional impact with other conditions [185].

Purpose Assessment of health-related quality of life across eight domains; comparison with population norms and other chronic disease groups.

Domains Physical Functioning (PF), Role-Physical (RP), Bodily Pain (BP), General Health (GH), Vitality (VT), Social Functioning (SF), Role-Emotional (RE), Mental Health (MH).

Scoring Each domain is scored 0–100, with higher scores indicating better health. Summary scores: Physical Component Summary (PCS) and Mental Component Summary (MCS).

ME/CFS-specific findings ME/CFS patients score significantly lower than population norms on all domains, with the most severe impairment in RP, PF, SF, and VT. ME/CFS SF-36 scores are comparable to or lower than scores for congestive heart failure, multiple sclerosis, and type 2 diabetes [185, 184].

Limitations Generic instrument not designed for ME/CFS; does not capture PEM, orthostatic intolerance, or cognitive symptoms specifically; ceiling effects may limit sensitivity in severely affected patients who are unable to complete the questionnaire.

C.2.2 Chalder Fatigue Scale

The Chalder Fatigue Scale is an 11-item self-report measure of fatigue severity.

Purpose Quantification of physical and mental fatigue severity.

Scoring 11 items scored on a 4-point Likert scale (bimodal scoring: 0, 0, 1, 1) or a 4-point continuous scale (0–3). Total score ranges from 0 to 11 (bimodal) or 0 to 33 (Likert).

Limitations Developed as a general fatigue measure, not specific to ME/CFS. Does not distinguish ME/CFS-type fatigue from fatigue due to depression, sleep disorders, or other causes. Used as a primary outcome in the controversial PACE trial [238], which has been criticized for using recovery thresholds that overlapped with entry criteria [182]. Not recommended as a sole outcome measure in ME/CFS trials.

C.3 Objective Tests

C.3.1 Two-Day Cardiopulmonary Exercise Testing (2-Day CPET)

Two-day CPET is the gold-standard objective test for demonstrating PEM and is the only test that can objectively quantify the exercise intolerance characteristic of ME/CFS [1].

Purpose Objective demonstration of post-exertional physiological impairment; documentation of reduced exercise capacity for disability evaluation; research quantification of metabolic dysfunction.

Protocol Two maximal graded exercise tests on consecutive days, typically on a cycle ergometer:

1. Day 1: Standard incremental exercise test to volitional exhaustion. Measures peak VO_2 , anaerobic threshold (AT/VT1), peak workload, and respiratory exchange ratio.
2. Day 2: Identical protocol repeated 24 hours later.

Interpretation In healthy controls and most other chronic diseases, day-2 performance equals or exceeds day-1 performance. In ME/CFS, day-2 performance is significantly reduced:

- Peak VO_2 decreases by $\geq 8\%$ (clinically significant decline)
- Anaerobic threshold decreases, indicating earlier metabolic shift to glycolysis
- Peak workload and exercise duration decrease

Clinical significance The day-2 decrement is objective, reproducible, and specific to ME/CFS among studied conditions. Provides strong evidence for PEM in disability evaluations.

Limitations Maximal exercise testing is contraindicated in some severely affected patients; provokes PEM lasting days to weeks; limited availability; requires specialized equipment and trained personnel. Not suitable for serial monitoring due to the PEM it induces.

C.3.2 Home-Based Assessment Protocols for Severe ME/CFS

Standard clinic-based diagnostic procedures are poorly tolerated by severe and very severe ME/CFS patients (Bell score ≤ 30), with $>60\%$ unable to complete inpatient protocols due to PEM [104]. The ACHTSAM study [104] is the first protocol to systematically evaluate which assessments can be safely administered through home visits, using a staged approach that orders procedures from low to high burden with mandatory rest periods.

Low-burden assessments (≤ 5 min, supine-tolerant): Resting ECG, pupillography, osteosonography (bone density), bioelectrical impedance body composition, near-infrared spectroscopy (NIRS) for muscle oxygenation, light activity sensor.

Moderate-burden assessments (5–15 min): HRV with paced breathing, Schellong orthostatic test, handgrip dynamometry, blood sampling, salivary cortisol.

High-burden assessments (25–30 min, mental/physical exertion): Cognitive testing (MoCA, TMT-B, SDMT), EndoPAT endothelial function (peripheral arterial tonometry), neurocognitive/psychological assessment.

Design principles Assessments proceed in burden order; supine procedures precede seated/standing tests; each procedure includes post-assessment perceived exertion rating; patients may pause or terminate at any time.

Tolerability hypothesis Non-invasive supine-position assessments are expected to achieve $\geq 80\%$ completion, while high-burden tests requiring sustained mental exertion or standing are expected to achieve $<30\%$.

Status Protocol published; results expected mid-2026.

C.3.3 Tilt Table Testing

Tilt table testing evaluates autonomic cardiovascular regulation during orthostatic stress.

Purpose Diagnosis of orthostatic intolerance, postural orthostatic tachycardia syndrome (POTS), and neurally mediated hypotension.

Protocol The patient rests supine for 10–20 minutes, then is passively tilted to $60\text{--}70^\circ$ for up to 45 minutes. Continuous heart rate and blood pressure monitoring throughout.

Diagnostic criteria

- **POTS:** Sustained heart rate increase ≥ 30 bpm (or ≥ 40 bpm in ages 12–19) within 10 minutes of tilt, without orthostatic hypotension
- **Neurally mediated hypotension:** Drop in systolic BP ≥ 20 mmHg or diastolic BP ≥ 10 mmHg, often with paradoxical bradycardia
- **Orthostatic hypotension:** Sustained drop in systolic BP ≥ 20 mmHg or diastolic ≥ 10 mmHg within 3 minutes of tilt

ME/CFS relevance Orthostatic intolerance is present in 50–90% of ME/CFS patients. Tilt table testing provides objective documentation and identifies the specific subtype, guiding treatment selection.

Alternative Active standing test (10-minute stand with serial HR and BP measurement) provides a simpler office-based screen, though less standardized.

C.3.4 Autonomic Function Tests

Additional autonomic assessments complement tilt table testing.

Heart rate variability (HRV) Analysis of beat-to-beat heart rate intervals from ECG or heart rate monitor recordings. Time-domain (SDNN, RMSSD) and frequency-domain (LF, HF, LF/HF ratio) metrics quantify sympathovagal balance. ME/CFS patients typically show reduced HRV, reduced HF power (parasympathetic), and elevated LF/HF ratio (sympathetic predominance) [523].

Valsalva maneuver Forced expiration against a closed glottis (40 mmHg for 15 seconds). The heart rate and blood pressure response has four phases testing baroreflex integrity. Abnormal responses indicate baroreflex failure.

Deep breathing test Heart rate response to deep breathing at 6 breaths/minute. The expiratory–inspiratory HR difference (E:I ratio) quantifies parasympathetic function. Reduced in ME/CFS.

C.4 Laboratory Tests

ME/CFS is currently a clinical diagnosis without a pathognomonic laboratory test. Laboratory testing serves two purposes: (1) excluding alternative diagnoses and (2) identifying treatable comorbidities.

C.4.1 Standard Exclusion Panel

The following tests are recommended to exclude conditions that can mimic ME/CFS [254, 249]:

- **Complete blood count:** Excludes anemia, leukemia, infection
- **Comprehensive metabolic panel:** Excludes renal/hepatic disease, electrolyte disorders
- **Thyroid function (TSH, free T4):** Excludes hypothyroidism/hyperthyroidism
- **Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP):** Screens for active inflammatory/autoimmune conditions
- **Ferritin:** Excludes iron deficiency (common comorbidity)
- **Vitamin B12 and folate:** Excludes deficiency-related fatigue
- **Cortisol (morning or ACTH stimulation test):** Excludes Addison’s disease (primary adrenal insufficiency)
- **Celiac serology:** Excludes celiac disease
- **Urinalysis:** Screens for renal disease, diabetes

△ Warning 1: Morning Cortisol Alone Does Not Exclude Post-Viral Secondary Adrenal Insufficiency

Standard morning cortisol screening is designed to detect primary adrenal insufficiency (Addison's disease), where cortisol is markedly low and ACTH is elevated. Post-viral secondary adrenal insufficiency—documented in ~40% of SARS-1 survivors [123] and in COVID-19 pituitary case series [125]—presents differently: cortisol falls in the low-normal range (typically not flagged as abnormal by laboratory reference ranges), and ACTH is low or inappropriately normal rather than elevated. This pattern is invisible to morning cortisol screening alone. In any post-COVID ME/CFS patient with fatigue disproportionate to other findings, unexplained hypotension, or a clinical picture consistent with cortisol insufficiency, dynamic testing should be considered: ACTH stimulation test (most accessible) or insulin tolerance test (ITT, gold standard for central AI). See Chapter 9, Section 9.1.2 for mechanistic context.

C.4.2 Extended Panel for Clinical Characterization

Additional tests characterize disease mechanisms but are not required for diagnosis:

- **Immunoglobulin levels** (IgG, IgA, IgM): Identifies humoral immune deficiency
- **Lymphocyte subsets** (CD4, CD8, NK cells): Characterizes immune cell populations
- **NK cell function assay**: Quantifies cytotoxic activity (research setting)
- **Autoantibody panel** (β_2 -adrenergic, muscarinic M3/M4 receptor antibodies): Identifies autoimmune subtype (specialized laboratories)
- **Viral serology** (EBV VCA IgG/IgM, EBNA, HHV-6 IgG): Documents prior/active herpesvirus infection
- **Tryptase**: Screens for mast cell activation
- **Vitamin D**: Common deficiency in housebound patients
- **Sleep study (polysomnography)**: Excludes primary sleep disorders (obstructive sleep apnea, narcolepsy)

C.4.3 Experimental Biomarkers

No validated diagnostic biomarker for ME/CFS exists, but several candidates are under investigation:

- **Metabolomics panels**: Reduced amino acids, altered lipid profiles, elevated lactate-to-pyruvate ratios [620, 265]
- **Cytokine panels**: Disease-duration-dependent profiles [334, 335]
- **Epigenetic markers**: DNA methylation signatures at specific CpG sites [198]
- **Two-day CPET**: While not a blood test, the day-2 decrement serves as a functional biomarker (Section C.3)

△ Warning 2: No Single Diagnostic Test Exists

ME/CFS remains a clinical diagnosis based on symptom patterns (post-exertional malaise as the cardinal feature) after exclusion of alternative explanations. No laboratory test, imaging study, or biomarker has been validated for routine diagnostic use. Patients and clinicians should be cautious of commercial tests marketed as ME/CFS diagnostics that have not undergone rigorous validation.

D Resources and Support

This appendix provides a comprehensive guide to ME/CFS patient organizations, online communities, advocacy resources, and prominent patient voices. Unlike the scientific literature cited throughout this document, these resources represent the patient community's perspective and lived experience—an essential complement to clinical and research knowledge.

Observation 112 (On Patient-Generated Knowledge). The ME/CFS patient community has developed sophisticated knowledge networks that often outpace formal medical understanding. Forums like Phoenix Rising and Science for ME regularly discuss research papers with clinical depth that would be impressive in any medical setting. Patient advocates have successfully challenged flawed research (notably the PACE trial), influenced government policy, and funded significant research initiatives. This appendix acknowledges that patient expertise is a legitimate and valuable form of knowledge.

D.1 International Patient Organizations

D.1.1 Major Global Organizations

Solve ME/CFS Initiative (Solve M.E.)

<https://solvecfs.org/>

US-based non-profit serving as a catalyst for research into ME/CFS, Long COVID, and other infection-associated chronic conditions. Operates the You+ME patient registry and biobank, funds research, and conducts policy advocacy. One of the largest and most influential ME/CFS organizations globally.

Open Medicine Foundation (OMF)

<https://www.omf.ngo/>

Founded by Linda Tannenbaum, whose son has ME/CFS. Directs the Scientific Advisory Board chaired by Ron Davis, PhD. Operates six international ME/CFS Collaborative Research Centers and funds the End ME/CFS Project. Known for patient-centered research approach and involvement of patients and family members at leadership level.

International Association for CFS/ME (IACFS/ME)

<https://www.iacfsme.org/>

International non-profit organization of clinicians, scientists, professionals, patients, and advocates. Publishes the peer-reviewed journal *Fatigue: Biomedicine, Health, and Behavior*, organizes international conferences, and promotes science-based care.

#MEAction Network

<https://www.meaction.net/>

International patient-led advocacy network fighting for health equality. Co-founded by filmmaker Jennifer Brea. Organizes the annual #MillionsMissing protests, provides

advocacy training, and supports local patient groups worldwide. Known for effective use of social media and grassroots organizing.

World ME Alliance

<https://worldmealliance.org/>

Global coalition of national ME organizations working to coordinate international advocacy efforts and share resources across countries.

D.1.2 European Organizations

European ME Alliance (EMEA)

<https://www.europeanmealliance.org/>

Pan-European patient organization representing 18 countries. Founded in 2008 as collaboration of national patient charities. Member of European Patients' Forum (EPF) and European Federation of Neurological Associations (EFNA). Conducts the Pan-European ME Patient Survey (over 11,000 respondents in 2024). Created the European ME Research Group (EMERG) and European ME Clinicians Council.

EUROMENE

<https://www.euromene.eu/>

European Network on ME/CFS—a COST (European Cooperation in Science and Technology) supported network of research groups across Europe. Published expert consensus on diagnosis, service provision, and care in Europe (2021).

D.2 National Patient Organizations by Country

D.2.1 Belgium

Remark 1 (Belgian Organizations). Belgian organizations are primarily Flemish-based, with limited French-language resources for Wallonia. In Belgium, the condition is typically referred to as “CVS” (Chronisch Vermoeidheidssyndroom) rather than ME. ◇

ME-Vereniging vzw

<https://www.me-vereniging.be/>

The ME Association (Belgium) raises awareness and strives for recognition of the disease. Organizes support groups in Antwerp, Hasselt, Ypres, and Nieuwrode. Operates an ME help-line. Co-founder of the European ME Alliance.

12ME

Belgian non-profit drawing attention to ME/CFS seriousness with a positive approach.

CVS contact groep vzw

<http://www.cvs-contactgroep.be/>

Aims at CFS and fibromyalgia patients, provides information on legitimate scientific research. Publishes quarterly magazine “Immune” and organizes meetings in Flanders.

RIZIV/INAMI-Recognized Diagnostic Centers

Historical Context Belgium originally established **five CVS reference centers** around 2002 at university hospitals (UZ Leuven, UZ Gent, UZ Antwerpen, UZ Brussel, and one in Wallonia). These centers operated until **2012**, when RIZIV abruptly cut funding. In 2014, a new system of “Multidisciplinary Diagnostic Centers” replaced them, but with reduced scope. As of 2024, only one center has signed the current convention.

UPC KU Leuven – Multidisciplinair Diagnostisch Centrum ME/CVS

Address: Leuvensesteenweg 517, 3070 Kortenberg

Phone: +32 2 758 05 11 (general); +32 2 758 16 77 (CVS consultation)

Email: cvs@upckuleuven.be

Website: <https://www.upckuleuven.be/nl/zorgaanbod/cvs>

Consultation hours: Tuesday 9:00–12:00, Wednesday 9:30–12:00 (by appointment)

As of 2024, this is the only center in Belgium with an official RIZIV/INAMI convention for ME/CVS. The center provides multidisciplinary diagnostic assessment and, if ME/CVS is confirmed, develops a care trajectory in collaboration with the patient’s GP. Referral must come from a GP who suspects ME/CVS. Convention runs until 2028.

Remark 2 (CBT-Based Treatment: Critical Context). The RIZIV/INAMI convention mandates cognitive behavioral therapy (CBT) and graded exercise therapy (GET) as the reimbursed treatments—an approach based primarily on the UK PACE trial, which has been heavily criticized for methodological flaws and subsequently disavowed by NICE guidelines (2021). Large patient surveys consistently report that GET worsens symptoms in the majority of ME/CFS patients, while CBT shows limited benefit for core symptoms. Belgian patient organizations have criticized this policy as outdated and potentially harmful. Patients should be aware that accepting the convention’s treatment pathway means committing to CBT/GET-based rehabilitation, which may not align with current international best practices emphasizing pacing and symptom management.

The convention offers reimbursement for up to 17 CBT sessions (individual: 50 min at €86.69; group: 90 min at €57.80 per participant—2024 rates). Maximum 8 sessions may be in group format. Contact RIZIV: Evi Declercq, +32 2 739 71 97, evi.declercq@riziv-inami.fgov.be. ◇

Other Clinical Resources

UZ Leuven

<https://www.uzleuven.be/nl/chronisch-vermoeidheidssyndroom-cvs>

University Hospital Leuven provides care for pronounced fatigue lasting more than 6 months that doesn’t improve with rest and significantly limits daily activities.

UZA – Centrum voor Gedragstherapie bij Vermoeidheid

<https://www.uza.be/behandeling/chronisch-vermoeidheids-syndroom-cvs>

University Hospital Antwerp’s Center for Behavioral Therapy for Fatigue (CGVF) treats patients with fatigue and functional complaints including CVS, chronic fatigue, fibromyalgia, and post-infectious fatigue.

UZ Gent CVS Network

UZ Gent coordinates an integrated care model for abnormal fatigue in East and West Flanders. Partners include AZ Alma, AZ Groeninge, Jan Yperman Ziekenhuis, AZ Maria Middelaers, AZ Sint-Jan, AZ Nikolaas, AZ Delta, and others. The GP serves as care process manager.

Sleep Medicine (Wallonia)

Centre Multidisciplinaire de Somnologie – Clinique Saint-Luc Bouge

Address: Rue Saint-Luc 8, 5004 Bouge (Namur)

Phone: +32 81 20 94 61

Email: labosommeil@slbo.be

Website: <https://slbo.be/services/centres-integres-et-pluridisciplinaires/centre-multidisciplinaire-de-somnologie/>

Established in 1993, this is a major French-language sleep medicine center in Wallonia. INAMI-accredited since 2002 for CPAP treatment and since 2018 for mandibular advancement devices. The multidisciplinary team includes pneumologists, neurologists, psychiatrists, ORL specialists, and psychologists. Accepts patients from age 15 with any sleep disorder. As of September 2025, waiting times reduced to approximately 6 weeks (compared to 6–8 months at many Belgian hospitals). Chief of Service: Dr Richard Frogner.

Remark 3 (Sleep Disorders and ME/CFS). While sleep clinics do not diagnose ME/CFS directly, they are valuable for ruling out primary sleep disorders (sleep apnea, narcolepsy, etc.) that can cause chronic fatigue, and for documenting the non-restorative sleep characteristic of ME/CFS. A sleep study may be part of the differential diagnosis workup. ◇

D.2.2 France

ASFC (Association française du Syndrome de Fatigue Chronique)

<https://www.asso-sfc.org/>

The only ME/CFS patient association approved by the French Ministry of Health (2015). Located in Lille. Works with a Scientific Board to welcome, inform, and support patients. Operates phone hotline, organizes regular patient meetings throughout France, and annual meetings with expert scientists.

EM Action France

French website reporting international ME news and research.

Millions Missing France

<https://millionsmissing.fr/>

French chapter of the #MillionsMissing movement.

Remark 4 (French Recognition). ME/CFS is not officially recognized by the French Department of Health, leading to under-diagnosis and lack of disability recognition. ◇

D.2.3 Luxembourg

No dedicated ME/CFS patient organization exists in Luxembourg as of 2025. Patients may connect with:

- Belgian or French organizations (French-language)
- German organizations (German-language)
- EUROMENE network for research connections
- European ME Alliance for pan-European advocacy

D.2.4 Germany

Deutsche Gesellschaft für ME/CFS

<https://www.mecfs.de/>

German Society for ME/CFS, founded in 2016, based in Hamburg. Run by volunteers advocating for patient rights and medical/social recognition. Organized the first Parliamentary Expert Discussion on ME/CFS in the Bundestag (March 2020). Successfully lobbied for ME/CFS and Long COVID mention in federal government coalition agreement (2021). Successfully challenged the German “Tiredness” guideline’s recommendations for GET and CBT.

Fatigatio e.V.

<https://www.fatigatio.de/>

Federal Association ME/CFS, founded in 1993, based in Berlin. Over 2,900 members. Operates 15 regional self-help groups across German cities. Organizes annual hybrid ME/CFS conference with national and international experts.

Remark 5 (German Prevalence). Germany has seen dramatic growth in ME/CFS cases post-COVID: from an estimated 250,000 pre-pandemic to over 650,000 by end of 2024. ◇

D.2.5 Netherlands

ME/cvs Vereniging

<https://www.me-cvs.nl/>

Dutch association founded in 2005. The lowercase “cvs” deliberately underscores the desire for the medical world to stop using the name “Chronic Fatigue Syndrome.” Involved in international partnerships including UK ME/CFS Biobank, Solve ME, Open Medicine Foundation, and Charité Berlin.

ME Vereniging Nederland

Founded 2011. Membership open only to ME patients. Focus on improving living conditions and reducing social exclusion.

ME/ CVS-Stichting Nederland

Founded 1987. Receives government funding as recognized national ME/CFS patient organization.

Steungroep ME en Arbeidsongeschiktheid

Founded 1994. Support group focused on employment, education, disability, and benefits issues. Campaigns against exclusion from disability benefits.

The **Netherlands ME/CFS Cohort and Biobank (NMCB)** consortium is a national collaboration of research institutes, patient organizations, and clinical centers establishing a comprehensive patient cohort and biobank.

D.2.6 United Kingdom

ME Association

<https://meassociation.org.uk/>

One of the two largest UK ME/CFS charities. Provides information, advocacy, and services. Publishes quarterly magazine *ME Essential*. Funds the UK ME/CFS Biobank. Conducted major patient surveys (2010, 2015) documenting treatment experiences. Hosts local support groups nationwide.

Action for ME

<https://www.actionforme.org.uk/>

Founded 1987 as The M.E. Action Campaign. Merged with Association of Young People with ME in 2017. Funds high-quality research including the groundbreaking DecodeME study (largest ME/CFS genetic study ever, 15,000+ UK participants). Offers free support services including holistic healthcare services.

BACME (British Association of Clinicians in ME/CFS)

<https://bacme.info/>

Multidisciplinary organization for UK healthcare professionals delivering care to ME/CFS patients.

D.2.7 Ireland

Irish ME/CFS Association

<https://www.irishmecfs.org/>

Works to improve the situation for people with ME/CFS in Ireland. Notable advocate: Tom Kindlon (Assistant Chairperson), who has been housebound with severe ME for over 22 years. Known internationally for his extensive analysis and publications on the PACE trial and harms of graded exercise therapy.

Hope for ME & Fibro Northern Ireland

Founded 2011 by Joan McParland MBE, inspired by Tom Kindlon's work.

D.2.8 Norway

Norges ME Forening

<https://www.me-foreningen.no/>

Norwegian ME Association, founded 1987 by Ellen Piro. Represents over 6,000 ME

patients. Party-political independent organization. Works to ensure diagnosis based on Canadian Consensus Criteria. Member of European ME Alliance.

ME-Fondet

<https://www.me-fondet.no/>

Norwegian non-profit foundation dedicated to funding biomedical ME research. Supporting a promising daratumumab pilot study at Haukeland University Hospital.

Remark 6 (Norwegian Research Leadership). Norway has been a leader in ME/CFS research, pioneering innovative treatment approaches including the rituximab trials and subsequent work on autoimmunity. ◇

D.2.9 Denmark

ME Foreningen (Danish ME Association)

<https://me-foreningen.dk/>

National association since 1992. Works to increase knowledge in the Danish health-care system about ME as a physical/biomedical disease. Achieved unanimous Danish parliament vote to separate ME (ICD-10 G93.3) from Functional Disorders. Counseling available Wednesday/Friday 12–14 at +45 44 95 97 00.

D.2.10 Sweden

Riksföreningen för ME-patienter (RME)

Swedish national association for ME patients. Member of European ME Alliance.

D.2.11 Switzerland

ME/CFS Verein Schweiz

<https://www.mecfs.ch/>

Self-help organization founded 1993 in Zurich. Offers information platform, networking, and support. Hosts regular group meetings in several Swiss cities.

Schweizerische Gesellschaft für ME & CFS

<https://sgme.ch/>

Swiss Association for ME & CFS, founded 2019. Fights for recognition and adequate care. Conducts biennial comprehensive surveys on Swiss ME patient situations. First analysis published 2021.

Remark 7 (Swiss Diagnostic Challenges). Swiss research shows mean diagnosis time of 6.7 years, average 11.1 different appointments, 2.6 misdiagnoses, and 13.5% of patients traveling abroad to seek diagnosis. 90.5% of patients were told at least once that symptoms were psychosomatic. ◇

D.2.12 Spain

CONFESQ

<http://confederacion-fm-sfc.es/>

National Coalition of FM, CFS/ME, MCS, and EHS. Established 2004. Based in Jerez de la Frontera.

ONG-PEM (Asociación de Personas con Encefalomiелitis Miálgica)

Founded and run by severely ill patients. Exclusively represents Myalgic Encephalomyelitis.

Associació Catalana d'Afectats SFC/EM

<http://www.acsfcem.org/>

Catalonia-based patient association.

Spanish Facebook groups include VIVIR CON SFC/EM and #MillonesAusentes (Spanish #MillionsMissing).

D.2.13 Italy

CFS/ME Associazione Italiana

<http://www.stanchezzacronica.it/>

Founded 1991 by Prof. Umberto Tirelli in Udine—first Italian physician to identify CFS cases. Based at Centro di Riferimento Oncologico, Aviano.

Associazione Malati di CFS ODV

<http://www.associazioneecfs.com/>

Patient advocacy group founded 2004, based in Pavia. Part of Rare Disease Alliance (Alleanza delle Malattie Rare). Celebrated 20 years in 2024.

CFS/ME Organizzazione di Volontariato

<https://www.cfsme.it/>

Veneto-based patient organization.

CFS Italia Forum (<http://www.cfsitalia.it/>) provides Italian-language patient community and information exchange.

D.2.14 Australia

Emerge Australia

<https://emerge.org.au/>

National organization providing services, evidence-based education, advocacy, and research. Free national health and support line: 1800 865 321 (9am–4:30pm Mon–Fri). Offers online patient/carer education, peer support groups, RACGP CPD-approved healthcare professional education. Partners with Solve ME on AusME patient registry and biobank.

ME/CFS Australia

<https://mecfs.org.au/>

Peak body for patient-led ME/CFS charities. Focuses on federal government advocacy, research initiatives, and national awareness campaigns.

D.2.15 United States

American ME and CFS Society (AMMES)

<https://ammes.org/>

Serves patients and caregivers through support, advocacy, and education. Channels patient perspectives to government agencies and initiatives. Comprehensive website with links to international organizations.

U.S. ME/CFS Clinician Coalition

<https://mecfscliniciancoalition.org/>

Provides resources for medical providers caring for ME/CFS patients. Developed clinical guidance documents.

Bateman Horne Center

<https://batemanhornecenter.org/>

Medical center of excellence for ME/CFS and fibromyalgia. Founded by Dr. Lucinda Bateman. Focuses on diagnosis, treatment, research, and patient empowerment.

D.3 Research Centers and Specialized Clinics

D.3.1 Leading Research Centers

Stanford ME/CFS Collaborative Research Center

<https://med.stanford.edu/chronicfatiguesyndrome/>

Established 2013, directed by Ron Davis, PhD. Part of Stanford Genome Technology Center. Focus on developing objective diagnostic tests and treatments. Known for nanoneedle diagnostics development.

Columbia Center for Infection and Immunity

Columbia University.

Directed by W. Ian Lipkin, MD. ME/CFS research focus on infectious triggers and immune dysfunction.

Cornell ME/CFS Center for Enervating Neurolimmune Disease

Directed by Maureen Hanson, PhD. Research on mitochondrial function, immune cells, and microbiome.

Charité Fatigue Centrum

Berlin, Germany. <https://cfc.charite.de/>

Major European ME/CFS research and clinical center. Led by Prof. Carmen Scheibenbogen.

Uppsala University ME/CFS Collaboration

Sweden.

Led by Jonas Bergquist, MD, PhD. Focus on neurochemistry and analytical approaches.

D.3.2 Specialized Clinical Centers

Bateman Horne Center

Salt Lake City, Utah.

Clinical care with research integration. Founded by Dr. Lucinda Bateman.

Open Medicine Clinic

Mountain View, California.

Run by Dr. David Kaufman. Known for complex chronic illness expertise.

Haukeland University Hospital

Bergen, Norway.

Site of rituximab trials and ongoing autoimmunity research.

D.4 Online Communities and Forums

D.4.1 Discussion Forums

Phoenix Rising

<https://phoenixrising.me/> and <https://forums.phoenixrising.me/>

Founded by Cort Johnson. One of the most visited ME/CFS websites. Approximately 19,000 member accounts with 600 daily active members (2017). Covers dysautonomia, hormones, methylation, lifestyle management, relationships, and caregiver support.

Science for ME (S4ME)

<https://www.s4me.info/>

Independent, patient-led, international forum. Founded by Andy Devereux-Cooke. Each thread typically dedicated to a single research paper, enabling in-depth discussion. Notable members have included Jonathan Edwards, Tom Kindlon, Simon McGrath, and David Tuller. Advocates for patients as research partners.

Health Rising Forums

<https://www.healthrising.org/forums/>

Companion to Health Rising blog. Discussion of ME/CFS, fibromyalgia, chronic pain, IBS, and dysautonomia.

MEpedia

<https://me-pedia.org/>

Crowd-sourced encyclopedia of ME/CFS science and history. Creative Commons licensed. Categories include notable patients, citizen scientists, and ME/CFS history. Valuable reference for terminology, research summaries, and advocacy history.

D.4.2 Reddit Communities

r/cfs

<https://www.reddit.com/r/cfs/>

Primary ME/CFS subreddit. Research discussions, treatment experiences, and personal support. Active moderation maintaining distinction between ME/CFS and chronic fatigue symptom.

r/covidlonghaulers

Related community for Long COVID with significant ME/CFS overlap.

D.4.3 Facebook Groups

Major ME/CFS Facebook groups (search on Facebook):

- Chronic Fatigue Syndrome & Myalgic Encephalomyelitis ME Self Help Group (founded 2012)
- #MEAction state/regional chapters
- Pregnancy and Parenting with ME/CFS
- Caregiver Support groups
- Severe ME support groups
- Youth ME/CFS support (ages 13–21)

D.4.4 Other Platforms

Smart Patients ME/CFS Community

<https://www.smartpatients.com/communities/me-cfs>

Peer-to-peer support where patients and families share experiences and research.

NURA

Social network platform specifically for Long COVID, ME/CFS, and fibromyalgia patients, created by people with these conditions.

D.5 Prominent Patient Advocates and Content Creators

Observation 113 (The Patient Expertise Network). ME/CFS advocacy is largely driven by patients themselves, often working with extremely limited energy. The individuals listed here represent a fraction of the patient community dedicating their scarce functional capacity to improving conditions for all patients. Many severely ill patients contribute via social media, writing single tweets or posts that may represent their entire energy expenditure for a day.

D.5.1 Filmmakers and Documentarians

Jennifer Brea

Background American documentary filmmaker and activist. PhD student at Harvard when sudden illness left her bedridden.

Key work *Unrest* (2017)—Sundance award-winning documentary, Emmy-nominated, short-listed for Academy Award. Available free on YouTube (May 2023). Produced largely from bed, directing remotely with crews worldwide.

Advocacy Co-founder of #MEAction. Delivered highest-rated TED Talk at 2016 TED Summit (nearly 2 million views, 25+ languages).

Personal journey Later discovered craniocervical instability (CCI) and underwent spinal fusion surgery, experiencing significant improvement—highlighting ME/CFS subgroup heterogeneity.

Website <https://www.jenniferbrea.com/>

Dianna Cower (Physics Girl)

Background Science educator, YouTube channel with 2.8+ million subscribers.

Illness Contracted COVID-19, developed Long COVID/ME/CFS. Currently completely bed-bound, unable to care for herself. Also developed MCAS.

Advocacy 12-hour livestream (July 6, 2024) showing “a day in her life” with severe ME/CFS. Co-hosted by Ian Hecox and Simone Giertz. Raised \$150,000+ for Open Medicine Foundation. Livestream became top post on r/videos (27M subscribers).

Impact Brought ME/CFS awareness to mainstream audience unfamiliar with the condition.

Platform YouTube: Physics Girl; Twitter/X: @thephysicsgirl

D.5.2 Writers and Bloggers

Cort Johnson

Background Developed ME/CFS/FM in 1980s while in Environmental Studies program at UC Santa Cruz. MS in Environmental Studies from San Jose State University (2000).

Key work Founded Phoenix Rising (2004)—became most visited ME/CFS website by 2010. Left to found Health Rising (2012), broadening focus to include fibromyalgia. Produced 1000+ comprehensive blogs on ME/CFS and FM.

Recognition ProHealth’s Advocate of the Year (2015). IACFS/ME Special Services Award (2016). Described as “the quintessential patient advocate, breaking more news about this illness than many professional journalists.”

Website <https://www.healthrising.org/>

Social media Twitter/X: @CortJohnson

Jamison Hill

Background Former bodybuilder and certified personal trainer at Sonoma State University. Developed ME after mononucleosis in senior year (2010).

Illness severity By age 28, bedridden, unable to speak, eat solid food, or elevate body. Wrote on cellphone wearing tanning goggles to block light.

Publications *When Force Meets Fate: A Mission to Solve an Invisible Illness* (2021 memoir). Written for The Washington Post, The New York Times, Los Angeles Times, Men’s Journal, Vox, VICE, and others.

Media Featured in *Forgotten Plague* documentary, Netflix series (2018), WBUR Modern Love podcast, Dax Shepard’s Armchair Expert podcast.

Current status Improved with anti-virals, hydrocortisone, IV saline—not fully recovered but able to tell his story.

Website <https://jamisonwrites.com/>

Whitney Dafoe

Background Son of Dr. Ron Davis (Stanford geneticist) and Dr. Janet Dafoe. Former adventurer and photographer who traveled to all 50 states, India, Nepal, Ecuador.

Diagnosis ME/CFS diagnosed 2010.

Current severity One of the most severe ME/CFS cases documented. Cannot speak. Cannot tolerate contact with anyone but parents due to visual dysfunction. Fed by tube directly into stomach. Hasn't spoken in years.

Advocacy Despite severity, maintains blog, Facebook page, Instagram documenting life with severe ME/CFS. Won Gold at European Photography Awards (2022) for documentary series "The Living Death."

Impact His illness catalyzed his father's complete redirection of research focus: "I decided to terminate everything I was working on before Whitney got sick. Everything is ME/CFS now."

Website <https://www.whitneydafoe.com/>

Patreon <https://www.patreon.com/whitneydafoe>

Other Notable Bloggers

Suzan Jackson (Live with CFS)

Has ME/CFS since 2002; both sons also developed ME/CFS at ages 6 and 10. Blog focuses on living well despite chronic illness.

Mary M. Schweitzer, PhD (Slightly Alive)

Former history professor. Maintains ME and CFS Information Page with essays, reports, and conference summaries.

Naomi Whittingham (A Life Hidden)

UK-based, severe ME since age 12. Does interviews and supports brother Tom Whittingham's marathon fundraising for ME Research UK.

Laura's Pen

Blog covering Lyme disease, ME/CFS, and endometriosis awareness.

Super Pooped

ME/CFS awareness through art, crafts, and humor.

D.5.3 Researchers Who Are Patients or Family Members

Ron Davis, PhD

Position Professor of Biochemistry and Genetics, Director of Stanford Genome Technology Center.

Background Pioneered technology that powered the Human Genome Project. Over 64 biotechnology patents.

Personal connection Son Whitney has very severe ME/CFS.

Research pivot “I decided to terminate everything I was working on before Whitney got sick. Everything is ME/CFS now.”

Leadership Director of OMF Scientific Advisory Board. Established Stanford ME/CFS Collaborative Research Center (2013). His work helped prove ME/CFS is a biological disease.

Tom Kindlon

Background Very active young man (soccer, tennis, cricket, cross-country) until ME at age 16 (February 1989).

Current status Housebound for 22+ years. Uses wheelchair. Full-time carer: his mother Vera.

Expertise Studied Mathematical Sciences at Trinity College Dublin before dropping out. Extensive analysis and publications on PACE trial and harms of graded exercise therapy. Work available on ResearchGate and PubMed.

Role Assistant Chairperson, Irish ME/CFS Association.

Recognition OMF certificate of merit. Described as “a leader in the global ME/CFS community” who “initiated patient-led efforts to take a scientific approach to analyzing ME/CFS research.” Nominated for honorary degree at Trinity College Dublin.

Andy Devereux-Cooke

Role Patient, founder of Science for ME forum.

Research Research investigator on DecodeME study—demonstrating patient partnership in research.

D.5.4 Celebrity Advocates

Laura Hillenbrand

Author of *Seabiscuit* and *Unbroken*. Candid about ME/CFS struggles and medical misunderstanding.

Karin Alvtegen

Scandinavian author of psychological thrillers (*Missing*, *Betrayal*). ME/CFS has significantly shaped her life and career.

D.5.5 Euthanasia and End-of-Life Discussions

Remark 8 (Community Discourse on Quality of Life). The severity of ME/CFS has led to difficult conversations within the patient community about quality of life and end-of-life options. Some patients with very severe ME/CFS have publicly discussed or pursued medical assistance in dying in countries where it is legal (Belgium, Netherlands, Switzerland, Canada). These discussions reflect the profound suffering experienced by the most severely affected patients and the lack of effective treatments. ◇

- **Samuel (Austria, 2004–2026)** – Samuel developed very severe ME/CFS following a COVID-19 infection. In his final public statement, posted to Reddit 12 days before his death, he described his condition: “I must lie in bed 24 hours a day and cannot move too much, it must be permanently dark because I cannot tolerate light. I wear double hearing protection because I also cannot tolerate sounds. I cannot watch television or videos for even a second, as moving images overwhelm my nervous system and trigger unbearable suffering. I cannot listen to music or podcasts. I cannot even talk to my own mother, who cares for me, because listening is too exhausting and speaking has become completely impossible. I must communicate with pen and paper.” He described the physical suffering as “like drowning and burning at the same time” and noted that any exertion beyond his energy limits caused crashes leading to permanent deterioration. He highlighted systemic failures: no approved medications exist for ME/CFS, Austria has no dedicated treatment centers despite 1% of the population being affected, most physicians do not recognize the disease, and the pension authority (PVA) called patients “charlatans and freeloaders.” Samuel chose medical assistance in dying in Austria, passing away on January 30, 2026—his 22nd birthday. His final message: “ME/CFS kills!” (*ME/CFS TÖTET!*)

D.6 Podcasts

The Understanding ME/CFS Podcast

Apple Podcasts, Spotify

Hosted by Patrick Ussher (7-year ME/CFS patient, author of *Understanding ME/CFS & Strategies for Healing*). Weekly interviews with patients and experts. Covers research, treatments, quality of life, and recovery stories.

Chronically Complex: The #MEAction Podcast

<https://www.meaction.net/chronically-complex-meaction-podcast/>

Interviews influential voices in ME/CFS and Long COVID. Topics include books on complex chronic disease, #MillionsMissing, #StopRestPace, disability activism, and art from disabled artists. Notable guests: Ryan Prior (CNN journalist, *Forgotten Plague* filmmaker), Cynthia Adinig (Long COVID advocate, SolveME board member).

CFS Unravelled

By Dan Neuffer (recovered from ME/CFS). Interviews with recovered patients and expert practitioners.

Discomfort Zone (Invisible Not Broken)

Hosted by Jason, engineering graduate who developed fibromyalgia, ME/CFS, and POTS. Each episode explores what it means to be chronically ill and disabled.

This Podcast Will Kill You – Episode 137

“ME/CFS: What’s in a name? (A lot, actually)” (April 2024). Deep dive into biology, history, and current research.

Hope and Help for Fatigue & Chronic Illness

Mission to help people with post-viral syndromes including Long COVID and ME/CFS.

D.7 YouTube Channels and Video Resources

D.7.1 Patient-Focused Channels

CFS Health

32.7K subscribers. Founded by Toby Morrison. Multi-dimensional approach to ME/CFS and fibromyalgia recovery.

CFS Unravelled

53.5K subscribers. Dan Neuffer shares insights on ME/CFS, POTS, and fibromyalgia healing.

Understanding ME-CFS

Patrick Ussher's channel accompanying his podcast.

D.7.2 Organization Channels

Open Medicine Foundation

Research updates, patient stories, educational content.

Solve ME/CFS Initiative

10K subscribers. Research and advocacy updates.

Bateman Horne Center

15.6K subscribers. Clinical education and patient resources.

MEAction

3.3K subscribers. Advocacy updates and #MillionsMissing content.

D.7.3 Documentaries

Unrest

(2017) Jennifer Brea. Available free on YouTube (since May 2023). Essential viewing for understanding patient experience.

Forgotten Plague

Co-directed by Ryan Prior. Features Jamison Hill and other patients.

What About ME?

Earlier documentary on ME/CFS.

Hope to our Hands

(2020) Documentary about ME/CFS patients in Japan struggling for acknowledgment.

Living with Chronic Fatigue Syndrome

German/French documentary premiered on ARTE. Available in German and French.

D.8 Social Media Hashtags and Campaigns

D.8.1 Key Hashtags

#MillionsMissing	Primary advocacy hashtag for global protests
#MECFS	Standard disease hashtag
#pwME	“People with ME”
#SevereME	Focusing on severe/very severe patients
#MyalgicE	Short form for myalgic encephalomyelitis
#May12th	ME Awareness Day
#StopRestPace	Pacing advocacy
#TeachMETreatME	2024 campaign theme
#LongCovid	Related condition with significant overlap

D.8.2 #MillionsMissing Campaign

Annual global campaign for ME health equality, organized by #MEAction. May 12th is ME Awareness Day—patients gather (in-person and virtually) to demand recognition, research, and clinical care. In 2025, communities joined at the U.S. Capitol to advocate for protecting Medicaid, home care support, research funding, and open science.

The campaign highlights the “millions missing” from their own lives due to illness, and the millions of research dollars missing from funding.

D.9 Books by Patients and Advocates

D.9.1 Patient Memoirs

When Force Meets Fate: A Mission to Solve an Invisible Illness

Jamison Hill (2021). Former bodybuilder’s journey through severe ME/CFS.

The Puzzle Solver: A Scientist’s Desperate Quest to Cure the Illness that Stole His Son

Tracie White and Ron Davis (2021). Story of Ron Davis and Whitney Dafoe.

Understanding ME/CFS & Strategies for Healing

Patrick Ussher. Guide by a patient, companion to podcast.

The Long Haul

Ryan Prior. On Long COVID and ME/CFS advocacy.

D.9.2 Clinical and Reference Works

See also the scientific literature cited throughout this document. Patient organizations often maintain curated reading lists of accessible scientific overviews.

D.10 Clinical Trial Registries

ClinicalTrials.gov

<https://clinicaltrials.gov/>

Search for “myalgic encephalomyelitis” or “chronic fatigue syndrome.” Filter by recruiting status and location.

EU Clinical Trials Register

<https://www.clinicaltrialsregister.eu/>

European clinical trials database.

ME/CFS Research Register

<https://mecfs-research.org/>

Specialized registry tracking ME/CFS research internationally.

Questions to ask before participating:

- What are inclusion/exclusion criteria?
- What is the time commitment?
- Will travel be required? Is remote participation possible?
- What accommodations exist for severely ill participants?
- How will participant safety be monitored?
- Will results be shared with participants?

D.11 Patient Registries and Biobanks

You+ME Registry and Biobank

<https://youandme.solvecfs.org/>

Solve M.E.’s patient registry. Collects patient-reported data and biospecimens. International participation.

AusME Registry

Australian ME/CFS and Long COVID registry, partnership between Emerge Australia and Solve M.E.

UK ME/CFS Biobank

London School of Hygiene & Tropical Medicine. Funded partly by ME Association.

Netherlands ME/CFS Cohort and Biobank (NMCB)

National Dutch infrastructure for ME/CFS research.

DecodeME

UK-based genetic study with 15,000+ participants. Largest ME/CFS study ever conducted.

D.12 Disability and Legal Resources

D.12.1 General Guidance

Most national patient organizations provide country-specific guidance on:

- Disability benefits applications
- Workplace accommodations
- Educational accommodations
- Healthcare rights
- Insurance issues

D.12.2 Key Considerations

- ME/CFS is classified as a neurological disease by WHO (ICD-11: 8E49)
- Documentation of functional limitations is essential
- Some countries recognize ME/CFS for disability; others require extensive advocacy
- Patient organizations often provide template letters and case examples
- Legal advocacy organizations exist in some countries

The **Steungroep ME en Arbeidsongeschiktheid** (Netherlands) specifically focuses on employment and disability issues. The **ME Association** (UK) provides extensive guidance on UK benefits system.

D.13 Resource Evaluation Guidelines

Observation 114 (Navigating Information Quality). The ME/CFS information landscape includes high-quality patient-led resources alongside misinformation and exploitation. The patient community has developed sophisticated evaluation skills born of necessity.

D.13.1 Indicators of Reliable Resources

- Connection to established patient organizations
- Citation of peer-reviewed research
- Acknowledgment of uncertainty and ME/CFS heterogeneity
- Clear distinction between established knowledge and speculation
- Avoidance of cure claims
- Transparency about funding sources
- Respect for patient autonomy and pacing needs

D.13.2 Warning Signs

- Guaranteed cures
- Pressure to commit quickly or pay upfront
- Hostility to questions
- Rejection of biomedical model without evidence
- Promotion of graded exercise therapy without acknowledging PEM risks
- Claims that contradict major patient surveys
- No outcome data available
- Primarily selling products or services

Remark 9 (For Wallonia/Belgium Residents). French-language resources from ASFC (France), Swiss organizations, and Canadian French resources may supplement the primarily Flemish Belgian organizations. The European ME Alliance provides pan-European perspective and advocacy regardless of language. ◇

E Mathematical Model Details

This appendix provides the complete mathematical specifications for the models developed in Part V, including full parameter tables, derivations of key results, numerical methods, and sensitivity analysis procedures. Readers should consult the corresponding chapters for biological context and interpretation.

E.1 Complete Model Equations

E.1.1 Energy Metabolism Model

The energy metabolism model (Chapter 36) comprises 8 state variables. The complete ODE system is:

$$\frac{d[\text{ATP}]}{dt} = 2J_{\text{glyc}} + J_{\text{ATPsyn}} - J_{\text{demand}}(t) \quad (\text{E.1})$$

$$\frac{d[\text{ADP}]}{dt} = J_{\text{demand}}(t) - 2J_{\text{glyc}} - J_{\text{ATPsyn}} + J_{\text{AK,fwd}} - J_{\text{AK,rev}} \quad (\text{E.2})$$

$$\frac{d[\text{AMP}]}{dt} = J_{\text{AK,rev}} - J_{\text{AK,fwd}} \quad (\text{E.3})$$

$$\frac{d[\text{NADH}]}{dt} = 2J_{\text{glyc}} + 3J_{\text{Krebs}} - J_{\text{CI}} \quad (\text{E.4})$$

$$\frac{d[\text{Pyr}]}{dt} = J_{\text{glyc}} - J_{\text{PDH}} \quad (\text{E.5})$$

$$\frac{d\Delta\Psi}{dt} = \frac{1}{C_m}(4J_{\text{CI}} + 4J_{\text{CIII}} + 2J_{\text{CIV}} - n_{\text{ATP}}J_{\text{ATPsyn}} - J_{\text{leak}}) \quad (\text{E.6})$$

$$\frac{d[\text{ROS}]}{dt} = J_{\text{ROS}} - k_{\text{SOD}}[\text{SOD}][\text{ROS}] - k_{\text{GPx}}[\text{GPx}][\text{ROS}] \quad (\text{E.7})$$

$$\frac{dD}{dt} = k_D[\text{ROS}] \cdot \mathbb{I}_{[\text{ROS}] > \text{ROS}_{\text{thr}}} - k_{\text{rep}} \frac{[\text{ATP}]}{K_{\text{rep}} + [\text{ATP}]} \quad (\text{E.8})$$

where the proton stoichiometry coefficients (4, 4, 2) are the number of protons pumped per electron pair by Complexes I, III, and IV respectively (total 10 H^+ per NADH), $n_{\text{ATP}} \approx 8/3$ is the H^+/ATP ratio of ATP synthase, J_{AK} denotes the adenylate kinase equilibrium ($2\text{ADP} \rightleftharpoons \text{ATP} + \text{AMP}$, $K_{\text{eq}} \approx 0.44$), and J_{PDH} is the pyruvate dehydrogenase flux linking glycolysis to the Krebs cycle. The conservation constraints $[\text{ATP}] + [\text{ADP}] + [\text{AMP}] = A_{\text{total}}$ and $[\text{NAD}^+] + [\text{NADH}] = N_{\text{total}}$ reduce the independent variables to 6. The adenylate kinase equilibrium is maintained by setting $J_{\text{AK,fwd}} - J_{\text{AK,rev}} = k_{\text{AK}}(K_{\text{eq}}[\text{ADP}]^2 - [\text{ATP}][\text{AMP}])$.

E.1.2 Energy Metabolism Parameter Table

Table E.1 lists all parameters with healthy baseline values, ME/CFS ranges, units, and sources. Parameter values are drawn from published enzymology, metabolomics, and CPET data where available; parameters without direct experimental constraints are indicated.

Table E.1: Energy metabolism model parameters.

Parameter	Healthy	ME/CFS	Units	Source
$V_{\max, \text{PFK-1}}$	1.2	1.2	mM/min	Enzymology
$K_{0.5}^{\text{F6P}}$	0.1	0.1	mM	Enzymology
n_H (PFK-1)	2.5	2.5	–	Enzymology
K_i^{ATP}	1.0	1.0	mM	Enzymology
$V_{\max, \text{CI}}$	1.0	0.5–0.8	mM/min	[421]
K_m^{NADH}	0.05	0.05	mM	Enzymology
$\Delta\Psi_{\text{threshold}}$	110	110	mV	Biophysics
$J_{\text{leak},0}$	0.05	0.075–0.15	mM/min	Estimated
A_{total}	8.0	8.0	mM	Physiology
N_{total}	1.0	0.6–0.9	mM	[193]
k_{ROS}	0.01	0.01	min^{-1}	Estimated
k_{SOD}	10.0	10.0	$\text{mM}^{-1}\text{min}^{-1}$	Enzymology
k_D	0.001	0.001	min^{-1}	Estimated
k_{rep}	0.005	0.005	min^{-1}	Estimated

E.1.3 Immune System Model

The immune model (Chapter 37) comprises 12 state variables for cell populations and 6 for cytokines. The NK cell, T cell, and B cell dynamics are specified by Equations 37.1–37.12. The cytokine network is defined by the production and degradation terms in Equation 37.5. Full parameter tables for the immune model follow the same format as Table E.1; key parameters are listed below.

Table E.2: Selected immune model parameters.

Parameter	Healthy	ME/CFS	Units	Source
s_N (NK production)	50	50	cells/ μL /day	Physiology
$k_{\text{act},0}$ (NK)	0.2	0.2	day^{-1}	Estimated
k_{exh} (NK)	0.05	0.1–0.2	day^{-1}	[361]
k_{recov} (NK)	0.1	0.03–0.07	day^{-1}	Estimated
$\delta_{\text{IL-6}}$	0.5	0.5	h^{-1}	Pharmacokinetics
δ_{TNF}	0.7	0.7	h^{-1}	Pharmacokinetics
d_P (plasma cell)	0.003	0.003	day^{-1}	Immunology
λ_0 (reactivation)	0.001	0.005–0.02	day^{-1}	Estimated

E.1.4 Neuroendocrine Model

The HPA axis (Equation 38.1), autonomic (Equation 38.4), neurotransmitter (Equations 38.10–38.14), and sleep–wake (Equation 38.16) models contribute 14 additional state variables. Key parameters:

Table E.3: Selected neuroendocrine model parameters.

Parameter	Healthy	ME/CFS	Units	Source
σ_H (CRH)	10	10	pg/mL/h	Endocrinology
a_c (circadian)	0.4	0.15–0.25	–	[439]
n_F (feedback)	2.0	3.0–4.0	–	[782]
δ_F (cortisol)	0.08	0.08	h ^{−1}	Pharmacokinetics
G_S (baroreflex)	0.5	0.2–0.4	bpm/mmHg	[523]
r_{decay} (sleep)	0.05	0.02–0.04	h ^{−1}	Estimated
$v_{\text{IDO,basal}}$	0.01	0.01	mM/h	[356]

E.2 Parameter Estimation Methods

E.2.1 Maximum Likelihood Estimation

For the energy metabolism model, parameters are estimated by minimizing the weighted residual sum of squares between model predictions and CPET-derived measurements (peak VO_2 , anaerobic threshold, lactate kinetics). The objective function is:

$$\mathcal{L}(\theta) = -\frac{1}{2} \sum_{i=1}^N \left[\frac{(y_i - \hat{y}_i(\theta))^2}{\sigma_i^2} + \log(2\pi\sigma_i^2) \right] \quad (\text{E.9})$$

where y_i are observed values, $\hat{y}_i(\theta)$ are model predictions at parameter vector θ , and σ_i are measurement standard deviations. Optimization uses the Nelder–Mead simplex algorithm for initial exploration followed by gradient-based refinement (L-BFGS-B with box constraints on biologically plausible parameter ranges).

E.2.2 Bayesian Inference

Bayesian parameter estimation uses informative priors derived from published literature. For each parameter θ_j , the prior distribution encodes existing knowledge:

- **Well-characterized parameters** (enzyme K_m values, degradation rates): Log-normal priors with mean and variance from published enzymology
- **Moderately characterized parameters** (impairment factors α_{CI} , β): Uniform priors on biologically plausible ranges

- **Poorly characterized parameters** (symptom weighting coefficients): Weakly informative half-normal priors

Posterior sampling uses the No-U-Turn Sampler (NUTS), a variant of Hamiltonian Monte Carlo that automatically tunes the step size and trajectory length. Convergence is assessed by the $\hat{R}$ statistic ($\hat{R} < 1.01$ required) and effective sample size ($n_{\text{eff}} > 400$ per chain). Four independent chains of 2000 post-warmup samples each are used.

E.3 Numerical Methods

E.3.1 ODE Integration

The stiff ODE systems arising from the coupled multi-system model (42 state variables) are integrated using implicit methods. The recommended solver is the Radau IIA method (5th-order, L-stable), which handles the wide range of timescales present in the model (milliseconds for enzyme kinetics to hours for cytokine dynamics) without requiring manual timescale separation. Absolute and relative error tolerances are set to 10^{-8} and 10^{-6} respectively.

For the stochastic viral reactivation model, the Gillespie stochastic simulation algorithm (SSA) is used for the latent-to-lytic transition, coupled to deterministic ODE integration for the subsequent immune response. The hybrid scheme switches from SSA to ODE at the moment of reactivation, using the SSA-generated viral load as an initial condition for the ODE system.

E.3.2 Steady-State Computation

Steady states of the ODE system satisfy $\mathbf{f}(\mathbf{x}^*, \boldsymbol{\theta}) = \mathbf{0}$. These are computed using Newton's method with analytical Jacobian. Stability is determined by the eigenvalues of the Jacobian evaluated at $\mathbf{x}^*$: the steady state is stable if all eigenvalues have negative real part, and unstable otherwise. Bifurcation analysis (continuation of steady states as parameters vary) is performed using pseudo-arclength continuation to trace solution branches through turning points and detect Hopf bifurcations.

E.4 Sensitivity Analysis Results

Global sensitivity analysis uses Sobol indices computed via Saltelli's sampling scheme. For each output of interest (e.g., steady-state ATP, PEM severity after standardized exertion), the first-order index S_i quantifies the fraction of output variance attributable to parameter θ_i alone, and the total-order index S_{Ti} includes contributions from all interactions involving θ_i :

$$S_i = \frac{\text{Var}(\mathbb{E}[Y \mid \theta_i])}{\text{Var}(Y)} \quad (\text{E.10})$$

$$S_{Ti} = 1 - \frac{\text{Var}(\mathbb{E}[Y \mid \boldsymbol{\theta}_{\sim i}])}{\text{Var}(Y)} \quad (\text{E.11})$$

where $\boldsymbol{\theta}_{\sim i}$ denotes all parameters except θ_i . A sample size of $N(2p + 2)$ model evaluations is required, where p is the number of parameters and $N \geq 1000$ for convergent estimates. For the full 42-variable model with approximately 60 parameters, this requires $\sim 122,000$ model evaluations—computationally feasible given the sub-second integration time per evaluation.

Parameters with $S_{Ti} < 0.01$ are classified as insensitive and can be fixed at nominal values without affecting model predictions. Parameters with $S_i > 0.1$ are classified as influential and are prioritized for experimental measurement.

E.5 Structural Identifiability

Structural identifiability analysis determines whether model parameters can be uniquely estimated from the available output measurements, assuming noise-free data of arbitrary quantity. For the energy metabolism model, the measured outputs are [ATP], [lactate] (derived from [Pyr]), and VO_2 (proportional to J_{CIV}). Using the differential algebra approach, we construct the input–output equations by eliminating unmeasured state variables. Parameters appearing independently in the coefficients of these equations are structurally identifiable; parameters appearing only in combinations are structurally unidentifiable (only the combination can be estimated).

Analysis of the energy metabolism model reveals that: (1) $V_{\text{max,CI}}$ and K_m^{NADH} are individually identifiable from VO_2 data; (2) k_{ROS} and k_{SOD} are identifiable only as the ratio $k_{\text{ROS}}/k_{\text{SOD}}$ from ROS-related outputs; (3) the damage parameters k_D and k_{rep} are identifiable from longitudinal day-1/day-2 CPET data but not from single-time-point measurements. These identifiability results guide experimental design: measuring ROS directly (rather than inferring from downstream markers) would resolve the $k_{\text{ROS}}/k_{\text{SOD}}$ ambiguity.

E.6 Code Availability

The mathematical models described in Part V are specified as systems of ordinary differential equations with explicit parameter definitions (this appendix). Implementation in any scientific computing environment (Python/SciPy, MATLAB, Julia/DifferentialEquations.jl, R/deSolve) is straightforward from the equations provided. No proprietary software is required. The parameter tables in this appendix provide all values needed to reproduce the models.

For reproducibility, the recommended implementation stack is:

- **ODE integration:** Julia with DifferentialEquations.jl (Radau5 solver) or Python with SciPy solve_ivp (Radau method)

- **Bayesian inference:** Stan (via CmdStan or PyStan) for NUTS sampling, or Julia with Turing.jl
- **Sensitivity analysis:** SALib (Python) for Sobol index computation
- **Bifurcation analysis:** AUTO-07p or MatCont (MATLAB) for continuation

F Practical Supplement Guide

This appendix provides a practical reference for supplements commonly used in ME/CFS management, organized by target mechanism. All information is derived from the evidence reviewed in Chapter 23. This guide is intended as a reference for informed discussion between patients and their healthcare providers, not as a prescription.

△ **Warning 1: Medical Supervision Required**

Supplements can interact with medications, affect laboratory results, and produce adverse effects. All supplement decisions should be made in consultation with a qualified healthcare provider who is aware of the patient's complete medical history and medication list. The dosages listed below are derived from published studies and clinical protocols; individual requirements may differ.

F.1 Quick Reference Tables

F.1.1 Mitochondrial and Energy Support

Table F.1 lists supplements targeting energy metabolism dysfunction, the primary pathophysiological mechanism in ME/CFS (Chapter 6).

F.1.2 Immune Modulation

F.1.3 Neurological and Sleep Support

F.1.4 Gut Health

Evidence levels are defined as: **Moderate** = at least one RCT in ME/CFS population; **Low** = open-label studies, case series, or extrapolation from related conditions; **Very low** = mechanistic rationale only, no ME/CFS-specific clinical data.

Table F.1: Mitochondrial and energy support supplements.

Supplement	Typical Dose	Evidence	Mechanism and Notes
Coenzyme Q10 (ubiquinol)	200–400 mg/day	Moderate	ETC electron carrier; RCT showed reduced fatigue [388]. Take with fat-containing meal.
NAD ⁺ precursors (NR or NMN)	250–500 mg/day	Low	Replenishes NAD ⁺ pool; limited ME/CFS-specific data [193].
D-Ribose	5 g 2–3×/day	Low	ATP precursor; small open-label studies suggest benefit. Dissolve in water.
Acetyl-L-carnitine	1000–2000 mg/day	Low	Fatty acid transport into mitochondria; supports β -oxidation.
Alpha-lipoic acid	300–600 mg/day	Low	Antioxidant; Krebs cycle cofactor. R-lipoic acid form preferred.
B-complex vitamins	1×/day (balanced formula)	Low	Cofactors for energy metabolism; B2 (riboflavin) for Complex I, B3 (niacin) for NAD ⁺ .

Table F.2: Immune modulation supplements.

Supplement	Typical Dose	Evidence	Mechanism and Notes
Vitamin D3	2000–5000 IU/day	Moderate	Immunomodulatory; deficiency common in housebound patients. Monitor serum levels; target 40–60 ng/mL.
Vitamin C	500–1000 mg/day	Low	Antioxidant; immune cell support. Higher doses may cause GI upset.
Zinc	15–30 mg/day	Low	NK cell function; thymic hormone production. Long-term use requires copper co-supplementation.
Selenium	100–200 μ g/day	Low	Antioxidant selenoproteins; thyroid function. Do not exceed 400 μ g/day.
Quercetin	500–1000 mg/day	Low	Mast cell stabilizer; anti-inflammatory. May help MCAS-overlap symptoms.

Table F.3: Neurological and sleep support supplements.

Supplement	Typical Dose	Evidence	Mechanism and Notes
Magnesium (glycinate or threonate)	200–400 mg elemental/day	Low	Muscle relaxation; NMDA receptor modulation; sleep support. Glycinate for general use; threonate for cognitive symptoms.
Melatonin	0.5–3 mg at bedtime	Low	Circadian rhythm regulation [453]. Start low; higher doses not more effective.
Omega-3 fatty acids (EPA/DHA)	1000–2000 mg combined/day	Low	Anti-inflammatory; neuronal membrane support. Choose high-EPA formulations for mood.
L-Theanine	100–200 mg/day	Very low	GABAergic; promotes relaxation without sedation.

Table F.4: Gut health supplements.

Supplement	Typical Dose	Evidence	Mechanism and Notes
Probiotics (multi-strain)	10^9 – 10^{10} CFU/day	Low	Microbiome modulation; strain-specific effects [352]. Lactobacillus and Bifidobacterium strains most studied.
Butyrate (tributyrin or sodium butyrate)	300–600 mg 2–3×/day	Very low	Intestinal barrier support; anti-inflammatory [488]. Enteric-coated preferred.
L-Glutamine	5–10 g/day	Very low	Intestinal epithelial cell fuel; barrier integrity.

F.2 Supplement Interactions

F.2.1 Supplement–Supplement Interactions

Most supplements listed above can be taken concurrently without adverse interactions. Notable considerations:

- **Zinc and copper:** Long-term zinc supplementation (> 30 mg/day for > 8 weeks) can induce copper deficiency. Co-supplement with 1–2 mg copper if zinc exceeds 30 mg/day.
- **CoQ10 and blood thinners:** CoQ10 has structural similarity to vitamin K and may reduce warfarin efficacy. Monitor INR if taking both.
- **Iron and other minerals:** Iron inhibits absorption of zinc, calcium, and magnesium. Separate iron from other mineral supplements by ≥ 2 hours.
- **Alpha-lipoic acid and thyroid medication:** May reduce levothyroxine absorption. Separate by ≥ 4 hours.
- **Melatonin and immunosuppressants:** Melatonin has immunomodulatory properties; use with caution in patients on immunosuppressive therapy.

F.2.2 Supplement–Drug Interactions

Interactions with commonly prescribed ME/CFS medications:

- **Low-dose naltrexone (LDN):** No known interactions with the supplements listed above.
- **Beta-blockers:** CoQ10 may modestly reduce blood pressure; monitor if combining with propranolol or other antihypertensives.
- **SSRIs/SNRIs:** Omega-3 fatty acids may potentiate anticoagulant effects; 5-HTP (not listed above) should be avoided with serotonergic medications due to serotonin syndrome risk.
- **Fludrocortisone:** Magnesium supplementation is advisable as fludrocortisone can increase magnesium excretion.
- **Midodrine:** No significant interactions with listed supplements.

F.3 Quality and Sourcing

Supplement quality varies substantially because dietary supplements are not subject to the same regulatory standards as pharmaceuticals. Patients should prioritize products verified by independent testing organizations:

- **USP (United States Pharmacopeia):** Tests for identity, potency, purity, and dissolution
- **NSF International:** Certifies Good Manufacturing Practices compliance and contaminant testing
- **ConsumerLab:** Independent testing with publicly available results
- **Informed Sport/Informed Choice:** Tests for banned substances (relevant for athletes)

Red flags suggesting poor quality:

- Claims of “curing” or “treating” ME/CFS
- Proprietary blends without individual ingredient quantities
- Lack of third-party testing certification
- Unrealistically low prices for expensive ingredients (e.g., ubiquinol, NMN)
- Marketing that relies on testimonials rather than cited research

F.4 Starting a Supplement Protocol

ME/CFS patients are frequently sensitive to new substances, including supplements. A systematic introduction protocol reduces the risk of adverse reactions and enables identification of which supplements provide benefit:

1. **One supplement at a time:** Introduce each new supplement individually, with a minimum 1–2 week observation period before adding the next. This ensures that any reaction (positive or negative) can be attributed to the correct supplement.
2. **Start low:** Begin at one-quarter to one-half of the target dose and increase gradually over 1–2 weeks if tolerated. ME/CFS patients may respond to lower doses than the general population.
3. **Priority order:** Start with supplements that have the strongest evidence and target the patient’s dominant symptoms:
 - Fatigue-dominant: CoQ10, then NAD⁺ precursors, then D-ribose
 - Sleep-dominant: Magnesium glycinate, then melatonin
 - Immune/pain-dominant: Vitamin D (if deficient), then omega-3, then quercetin
 - GI-dominant: Probiotics, then butyrate
4. **Track responses:** Maintain a simple log of symptoms before and after each supplement introduction. A minimum 4-week trial at target dose is needed to assess efficacy; some supplements (especially CoQ10, vitamin D) require 8–12 weeks.
5. **Periodic reassessment:** Every 3–6 months, consider whether each supplement is still providing benefit. Discontinue one supplement at a time and observe for 2–4 weeks. If no worsening occurs, the supplement may be unnecessary.

F.5 When to Stop a Supplement

Discontinue a supplement and consult a healthcare provider if:

- New symptoms develop that correlate temporally with supplement introduction
- Gastrointestinal symptoms (nausea, diarrhea, cramping) persist beyond the first week
- Allergic reaction signs appear (rash, itching, swelling, breathing difficulty)
- No discernible benefit after an adequate trial period (4–12 weeks depending on supplement)

- Laboratory values move outside reference ranges (e.g., vitamin D > 80 ng/mL, selenium > 200 µg/L)
- Cost becomes prohibitive relative to perceived benefit

⚠ Limitation 1: Evidence Gaps in ME/CFS Supplementation

Most supplements used in ME/CFS management lack randomized controlled trial evidence specific to ME/CFS populations. The recommendations in this appendix are based on a combination of limited ME/CFS-specific data, mechanistic rationale from the pathophysiology described in Part II, and extrapolation from related conditions (fibromyalgia, mitochondrial diseases, post-viral fatigue). Patients should be informed that supplementation is empirical and that individual responses are unpredictable.

G Research Synthesis Tables

G.1 Major Studies Summary

This section synthesizes key research findings integrated from literature reviews, including papers identified through systematic searches, community-reported studies, and recent publications (2019–2025).

G.1.1 Molecular and Cellular Mechanisms

Table G.1: Molecular Mechanism Studies in ME/CFS

Study	Design	Sample	Key Findings	Implications	Certainty
Wang 2023 [2]	Case-control; muscle biopsy	n=14 ME/CFS, n=10 controls	WASF3 protein elevated; inverse correlation with Complex IV (r=-0.55, p=0.005); shRNA knock-down restores function	WASF3 is druggable target; mechanism is reversible	MODERATE (pending replication)
Lim 2020 [201]	2-day CPET; repeated measures	n=51 ME/CFS, n=10 sedentary controls	VO ₂ max reduced 25% on Day 2 in ME/CFS; controls unchanged; ventilatory threshold reduced	Objective biomarker; 24-72h delayed impairment	HIGH (replicated)
Syed 2025 [189]	Systematic review	Multiple studies	Mitochondrial dysfunction across oxidative phosphorylation, ATP synthesis, metabolomics	Converging evidence for mitochondrial pathology	MODERATE-HIGH (meta-analytic)
Phair 2019 [135]	Metabolomics modeling	n=52 ME/CFS, n=45 controls	IDO metabolic trap hypothesis; tryptophan-kynurenine pathway disruption	Potential therapeutic target (IDO inhibitors)	MODERATE (hypothesis; needs validation)

G.1.2 Viral and Infectious Triggers

G.1.3 Immune Dysfunction Studies

Table G.2: Viral Association Studies

Study	Design	Sample	Key Findings	Evidence Level
Hwang 2023 [248]	Systematic review + meta-analysis	64 studies; n=4,971 ME/CFS, n=9,221 controls	18 viral species assessed; strongest associations: Borna (OR≥3.47), HHV-7 (OR>2.0), parvovirus B19 (OR>2.0), enterovirus (OR>2.0), coxsackie B (OR>2.0)	HIGH (meta-analytic; replicated)
Chia 2005 [832]	Observational; stomach biopsy	n=165 ME/CFS patients	Enterovirus detected in 82% of ME/CFS patients via stomach biopsy immunostaining; correlation with symptom severity	MODERATE (specialized technique; replication needed)
Gottschalk 2023 [804]	Case series; observational	n=42 Long COVID patients	LDN (4.5mg) improved fatigue, brain fog, PEM in 78% of Long COVID patients within 2 months	LOW-MODERATE (observational; no control group)

Table G.3: Immune System Studies in ME/CFS

Study	Design	Sample	Key Findings	Certainty
Fluge 2019 [505]	Phase III RCT (RituxME trial)	n=152 ME/CFS	Rituximab (B-cell depletion) showed NO benefit vs placebo; placebo response 35%, rituximab 26%	HIGH (definitive negative result)
Rekeland 2024 [621]	Long-term follow-up of RituxME	Original cohort; n=152 6-year follow-up	No long-term benefit from rituximab confirmed; subset analysis revealed no responder subgroups	HIGH (confirms Fluge 2019)
Bulbule 2024 [805]	Systematic review	Multiple NK cell studies	Reduced NK cell cytotoxicity consistently reported across studies; correlation with symptom severity	MODERATE-HIGH (consistent finding)

G.2 Biomarker Studies Summary

Table G.4: Validated and Proposed Biomarkers for ME/CFS

Biomarker	Measurement	Finding	Clinical Utility	Validation Status
2-Day CPET	VO ₂ max Day 1 vs Day 2	25% reduction Day 2 in ME/CFS [201]	Objective PEM documentation; disability assessment	VALIDATED (replicated)
WASF3 protein	Muscle biopsy immunoblot	Elevated in ME/CFS; inverse correlation with Complex IV [2]	Research tool; potential treatment target	PRELIMINARY (n=14; needs replication)
NK cell cytotoxicity	Flow cytometry; cytotoxic assay	Reduced across multiple studies [805]	Immune dysfunction marker	MODERATE (consistent but variable)
Viral serology	PCR, immunostaining	Enterovirus in 82% stomach biopsies [832]; multiple viral associations [248]	Subset identification (viral-onset)	MODERATE (specialized techniques)
Tryptophan-kynurenine	Plasma metabolomics	IDO metabolic trap [135]	Potential treatment stratification	HYPOTHESIS (needs validation)

G.3 Treatment Trials Summary

G.3.1 Pharmacological Interventions

Table G.5: Pharmacological Treatment Evidence in ME/CFS

Intervention	Study Type	Sample	Findings	Recommendation	Evidence
Low-Dose Naltrexone (LDN)	Observational	n=218 [263]; n=42 Long COVID [804]	73.9% positive response (ME/CFS); 78% improved (Long COVID); improved vigilance, alertness, physical/cognitive performance	Consider trial; 3.0–4.5mg/day	MODERATE (large observational; no RCT)
Rituximab (B-cell depletion)	Phase III RCT	n=152 [505]; 6-year follow-up [621]	NO BENEFIT; placebo 35% response > rituximab 26%; no long-term benefit	DO NOT USE	HIGH (definitive negative)
Graded Exercise Therapy (GET)	Multiple studies; patient surveys	Patient harm reports; PACE trial discredited	Causes deterioration in many patients; violates PEM physiology	HARMFUL; contraindicated	HIGH (consensus; patient evidence)

G.3.2 Patient-Reported Interventions

These interventions lack formal RCT validation but have plausible mechanisms and multiple independent patient reports. They require medical supervision and formal clinical trials.

Table G.6: Patient-Reported Interventions Requiring Clinical Validation

Intervention	Reported Dose		Reported Benefits	Plausible Mechanism		Research Status
Nicotine (low-dose)	2–4mg/day (gum, patch)		Rapid brain fog improvement (hours to days); multiple independent reports	Alpha-7 modulation; anti-inflammatory; mitochondrial calcium regulation (ch19 §26.6.2)	nAChR	HYPOTHESIS-GENERATING; needs RCT; addiction risk
Methylene blue	1–5mg/day (very low dose)		Smell restoration, brain fog reduction within 1 week	Enhances electron transport; reduces oxidative stress; indirect benefit despite Complex IV dysfunction (ch19 §26.6.6)		HYPOTHESIS-GENERATING; dose-finding needed
Ketogenic diet	Strict keto		Dramatic improvement in subset; "medication-free" in some cases	Ketone bodies provide alternative fuel (acetyl-CoA) without glucose; reduces oxidative stress (ch19 §84)		ANECDOTAL; subset-specific; needs stratified trial
Pyruvate (prophylactic)	1–2g pre-exertion		Proposed to prevent PEM crashes	Provides pyruvate directly for TCA cycle; skips glycolysis requirement; used by athletes (ch19 §88)		SPECULATIVE; testable in RCT
NAD+ precursors	NR 300–1000mg/day; NMN 250–500mg/day		Proposed for post-exertional recovery	Boosts lactate dehydrogenase; accelerates lactate clearance; improves mitochondrial NAD+/NADH ratio (ch19 §90)		SPECULATIVE; mechanistically sound; testable

G.3.3 Comorbidity Management

Table G.7: Comorbidities Frequently Misdiagnosed as ME/CFS

Condition	Diagnostic Test	Presentation Overlap	Clinical Implication
Sleep Apnea	Polysomnography (overnight sleep study)	Fatigue, cognitive dysfunction, unrefreshing sleep; patient reports describe years of misdiagnosis	CPAP treatment can resolve symptoms; should be standard workup
Lyme Disease (European species)	European Lyme serology panel	Chronic fatigue, PEM-like symptoms; 10-year misdiagnosis reported	Long-cycle antibiotics "significantly helpful"; requires regional-specific testing (ch19 §107)
Hypermobile EDS (hEDS)	Beighton score; clinical assessment	Joint hypermobility, easy bruising, fatigue, POTS overlap; "100-fold underdiagnosed"	Physical therapy adaptations; affects pacing strategies (ch19 §??)
Mast Cell Activation (MCAS)	Tryptase levels; clinical criteria	Allergic symptoms, flushing, GI issues, fatigue	H1/H2 blockers, mast cell stabilizers may help; potential mito-immune link (ch19 §26.6.11)
ADHD + hEDS overlap	Clinical assessment	Shared genetic factors proposed; frequent co-occurrence	May represent distinct phenotype requiring different management (ch19 §??)

G.4 Pathophysiology Evidence Summary

G.4.1 Converging Evidence for Core Mechanisms

G.4.2 Patient-Derived Clinical Insights

Community-reported patterns from online forums, patient advocacy groups, and Hacker News discussions reveal clinical insights not yet validated in formal research but with high practical utility.

G.4.3 Research Gaps and Controversies

G.4.4 Cross-Domain Medical Parallels

Table G.11 summarizes validated interventions from other medical fields with phenomenological overlap to ME/CFS, as detailed in Chapter 26 Section 26.5.

Table G.8: Evidence Strength for Proposed Pathophysiological Mechanisms

Mechanism	Supporting Evidence	Key Studies/Findings	Gaps	Strength
Mitochondrial dysfunction	ATP depletion, Complex IV deficits, delayed recovery	WASF3 elevation [2]; 2-day CPET [201]; systematic review [189]	Causation vs consequence; specific complex deficits vary	HIGH
Post-exertional malaise (PEM)	Objective VO ₂ max reduction Day 2; 24–72h delay	2-day CPET 25% reduction [201]; patient "<5 crash rule"	Molecular trigger; why delayed; recovery kinetics	HIGH
Viral triggers	Multiple viral associations; persistent infection	Meta-analysis OR 2.0–3.47 [248]; enterovirus 82% [832]	Why only subset; mechanism of chronicity; viral clearance failure	MODERATE-HIGH
Immune dysfunction	NK cell reduction, cytokine dysregulation	NK cytotoxicity reduced [805]; rituximab failure [505]	Primary vs secondary; T-cell role; autoimmunity	MODERATE
Autonomic dysfunction (POTS, OI)	Orthostatic intolerance 70–90% prevalence	Blood volume reduction; baroreceptor dysfunction	Connection to mitochondria; causation	HIGH
Neuroinflammation	Brain fog, cognitive impairment, hypoperfusion	Patient reports; imaging studies	Mechanisms; biomarkers; treatment targets	MODERATE
ER stress-WASF3 pathway	Viral infection → ER stress → WASF3 upregulation → Complex IV damage	Proposed pathway integrating viral triggers [248] and WASF3 [2] (ch19 §26.6.4)	Validation needed; ER stress markers; intervention trials	HYPOTHESIS
Metabolic trap (IDO pathway)	Tryptophan-kynurenine disruption	Phair modeling [135] (ch06 §6.7)	Replication; causation; therapeutic validation	HYPOTHESIS

Table G.9: Patient-Discovered Patterns and Clinical Rules

Pattern/Rule	Description	Clinical Implication	Validation Status
"<5 crashes per year" rule	Exceeding energy limits >5 times/year causes irreversible worsening	Strict pacing is non-negotiable; crashes have cumulative damage (ch14b §19.3.3)	OBSERVATIONAL; matches 2-day CPET pathology
Caffeine sensitivity changes	Pre-illness caffeine tolerance reverses post-illness; caffeine worsens crashes in many patients	Avoid caffeine or use minimally; may indicate adenosine receptor changes	ANECDOTAL; widely reported
24–72 hour PEM delay	Symptom crash occurs 1–3 days post-exertion, not immediately	Activity tracking must account for delayed consequences; "you won't know until Day 2"	VALIDATED by 2-day CPET [201]
Sleep apnea masquerading as ME/CFS	Years of ME/CFS diagnosis resolved with CPAP in subset	Polysomnography should be standard workup (ch19 §106)	CASE REPORTS; diagnostic importance
EDS/MCAS overlap	High comorbidity; "100-fold underdiagnosed"; shared symptoms	Screen for Beighton score, tryptase, allergic symptoms (ch19 §??)	CLINICAL OBSERVATION; needs epidemiological study
Nicotine rapid effect	Brain fog improvement within hours to days at 2–4mg	Suggests cholinergic or anti-inflammatory mechanism; testable in RCT (ch19 §26.6.2)	ANECDOTAL; multiple independent reports
Ketogenic diet subset response	Dramatic improvement in some; no effect or worsening in others	Heterogeneity suggests metabolic subtypes; stratified trial needed (ch19 §84)	ANECDOTAL; subset-specific
GET causes harm	Patient deterioration; violates PEM physiology; PACE trial discredited	Contraindicated; pacing is evidence-based alternative (ch14b §19.3.3)	VALIDATED; consensus

Table G.10: Major Research Gaps in ME/CFS

Gap	Current Status	Research Need
Why viral infection triggers chronic disease in subset	Multiple viral associations proven [248]; mechanism unknown	Longitudinal studies post-viral infection; genetic susceptibility; immune response profiling
WASF3 mechanism and reversibility	WASF3 elevated; shRNA reversal shown [2]; n=14	Replication in larger cohort; WASF3 inhibitor trials; longitudinal tracking
Why PEM is delayed 24–72 hours	Objective 2-day CPET shows delay [201]; molecular trigger unknown	Mitophagy markers; ATP kinetics; lactate clearance; serial muscle biopsies
Heterogeneity and subtypes	Clinical presentation varies; treatment responses differ	Cluster analysis; biomarker-based stratification; metabolomics subtyping
Why B-cell depletion failed but LDN helps	Rituximab negative [505]; LDN observational positive [263]	T-cell vs B-cell role; LDN mechanism (opioid vs immune); RCT of LDN
Connection between mitochondria and immune dysfunction	Both systems affected; unclear if linked or parallel	Mast cell-mitochondrial crosstalk; cytokine effects on oxidative phosphorylation
Reversibility and spontaneous remission	Rare spontaneous remission; WASF3 potentially reversible	Remission biomarkers; reversibility mechanisms; intervention timing

Table G.11: Cross-Domain Medical Interventions Applicable to ME/CFS

Source Field	Shared Feature	Intervention	ME/CFS Application	Implementation Status
Sports Medicine	Muscle metabolic stress, lactate accumulation	ORS, magnesium, Acetyl-L-carnitine, D-ribose	Lactate clearance, ATP support, cramp reduction	IMPLEMENTED; evidence-based
Altitude Medicine	Tissue hypoxia, exercise intolerance	Iron optimization (ferritin >100), acetazolamide, breathing techniques	Oxygen delivery, cerebral function	PARTIAL; iron standard; acetazolamide case reports
ICU Recovery (PICS)	Profound weakness, cognitive impairment, metabolic depletion	Micronutrient repletion (B1, C, D, Mg, Zn, Se), NAC, high protein	Metabolic support, oxidative stress, muscle preservation	IMPLEMENTED; nutritional protocols
Space Medicine	Orthostatic intolerance, deconditioning, blood volume loss	Compression garments, horizontal exercise, fluid/salt loading	POTS management, reconditioning, blood volume expansion	IMPLEMENTED; POTS protocols
Chronic Medicine	Pain Central sensitization, quality of life impairment	LDN, gabapentinoids, acceptance strategies	Pain reduction, central sensitization, pacing validation	PARTIAL; LDN evidence moderate
Geriatric Frailty	Multi-system decline, weakness, falls risk	Vitamin D optimization, protein supplementation, mobility aids without stigma	Frailty prevention, function optimization, assistive devices	IMPLEMENTED; acceptance of limitations

G.5 Quick Reference: Evidence-Based Treatment Summary

Table G.12 provides a rapid-access summary for clinicians and patients, organized by evidence strength and implementation tier.

Usage Notes for Table G.12.

- **Tier 1:** Implement immediately based on strong physiological rationale or consensus; low cost, high safety
- **Tier 2:** Consider trial for 3 months; monitor response; moderate evidence from observational studies or related conditions
- **Tier 3:** Experimental; discuss risks/benefits; await formal trials; mechanistically plausible but unvalidated
- **Start with Tier 1,** add Tier 2 interventions sequentially if no benefit after 3 months
- **Monitor responses** with symptom diary, objective measures (heart rate, activity tolerance)
- **Medical supervision required** for prescription medications, high-dose supplementation, or if multiple comorbidities present

Table G.12: Evidence-Based Treatment Quick Reference

Intervention	Typical Dose	Evidence Level	Primary Indication	Cost/Month	Tier
TIER 1: Strong Evidence, Immediate Implementation					
Pacing (energy envelope)	Individualized	HIGH (2-day CPET, consensus)	PEM prevention; core intervention	Free	1
Fluid/salt loading (POTS)	2.5–3L, 6–10g Na/day	HIGH (orthostatic physiology)	Orthostatic intolerance, blood volume	\$5	1
Compression stockings	20–30 mmHg waist-high	HIGH (POTS, space medicine)	Orthostatic intolerance	\$30–60 one-time	1
ORS (sports recovery)	500mL 2–3×/day	MODERATE (sports medicine)	Lactate clearance, hydration	\$5	1
Vitamin D	4000–5000 IU/day	MODERATE (ICU, geriatrics)	Immune function, muscle	\$5	1
Magnesium glycinate	300–400mg/day	MODERATE (ICU, sports)	ATP synthesis, cramps	\$10	1
B-complex (thiamine)	B1 100–300mg; B-complex	MODERATE (ICU critical care)	Aerobic metabolism, neurological	\$10	1
TIER 2: Moderate Evidence, Consider Trial					
CoQ10 + Acetyl-L-carnitine	200mg CoQ10; 500–1000mg ALC	MODERATE (mitochondrial support)	ATP production, fat oxidation	\$40–60	2
Iron optimization	Target ferritin 100–200	MODERATE (altitude medicine)	Oxygen transport, dopamine synthesis	\$10–15	2
NAC	600mg 2×/day	MODERATE (ICU, oxidative stress)	Glutathione support, oxidative stress	\$15–25	2
Vitamin C	1000–2000mg/day divided	MODERATE (ICU sepsis protocols)	Antioxidant, immune support	\$10	2
Zinc + selenium	15–30mg Zn; 200µg Se	MODERATE (ICU)	Immune function, antioxidant	\$10	2
LDN	3.0–4.5mg/day	MODERATE (n=218 observational)	Fatigue, brain fog, PEM	\$20–40	2
TIER 3: Emerging/Speculative, Needs Validation					
Pyruvate (prophylactic)	1–2g pre-exertion	SPECULATIVE (mechanistic rationale)	PEM prevention	\$15–25	3
NAD+ precursors (NR/NMN)	NR 300–1000mg; NMN 250–500mg/day	SPECULATIVE (lactate clearance hypothesis)	Post-exertional recovery	\$40–60	3
Methylene blue	1–5mg/day	SPECULATIVE (patient reports)	Brain fog, mitochondrial enhancement	\$10–20	3
Acetazolamide	125–250mg 2×/day	SPECULATIVE (altitude medicine)	Oxygenation, cognitive function	Rx required	3
D-ribose	5g 2–3×/day	SPECULATIVE (sports medicine)	ATP precursor	\$25–40	3
CONTRAINDICATED: Evidence of Harm					
Graded Exercise Therapy (GET)	N/A	HIGH (patient harm, PACE discredited)	HARMFUL; causes deterioration	N/A	—
Rituximab (B-cell depletion)	N/A	HIGH (Phase III RCT negative)	No benefit; placebo superior	N/A	—

G.6 Selective Energy Dysfunction Hypothesis Research Materials

The Selective Energy Dysfunction Hypothesis (see Chapter 6 Section 6.3 and Chapter 34 Section 34.1) has generated six research deliverables available in the project staging area (five completed, one planned). These materials are designed to facilitate hypothesis testing and clinical translation.

G.6.1 Patient Assessment Tools

Hair and Nail Health Survey. A comprehensive 649-line survey instrument designed to test the prediction that autonomous peripheral processes (hair/nail growth) are preserved in ME/CFS while CNS-dependent processes are impaired. The survey includes:

- Demographics and disease characteristics stratified by Bell Scale severity
- Hair health assessment (growth rate, thickness, quality, loss patterns)
- Nail health assessment (growth rate, quality, appearance)
- Correlation tracking with disease activity changes
- Confounder screening (nutrition, medications, hormones)

Location: content-staging/survey-hair-nail-health.md

Target population: 200 ME/CFS patients (50 each severity level) + 100 healthy controls + 100 disease controls

Expected outcomes: Hair/nail growth rates should be statistically equivalent to controls despite severe functional impairment, providing objective evidence for selective (not global) dysfunction.

PEM Self-Tracking Protocol. A patient-friendly protocol for tracking Post-Exertional Malaise patterns to test the prediction that PEM severity correlates with CNS involvement in the triggering activity. Features dual-mode design:

- **Simple mode:** 3 data points (activity type, PEM occurrence, severity) for patients with severe brain fog
- **Detailed mode:** Activity categorization by CNS involvement, PEM severity across 5 dimensions, timeline tracking

Location: content-staging/protocol-pem-tracking.md

Key prediction: Cognitive exertion (pure CNS) should cause more severe PEM than passive activities (minimal CNS demand).

Data collection period: 4–8 weeks for preliminary pattern identification

G.6.2 Existing Dataset Analysis

An inventory of 8 major ME/CFS datasets that could test hypothesis predictions without requiring new data collection:

- **NIH Intramural Study (Walitt 2024):** Deep phenotyping with brain imaging, autonomic testing, exercise physiology (n=17; highest priority for collaboration)
- **2-Day CPET Databases:** Multiple studies testing demand-response failure (100s of patients; immediate meta-analysis possible)
- **Van Campen Autonomic Studies:** CBF during orthostatic challenge (n=400+; replicates demand-response pattern)
- **UK Biobank ME/CFS Cohort:** Large-scale genetic and activity data (n=1,600; established access process)

Location: content-staging/existing-datasets-analysis.md

Contains: Dataset inventory table, prediction-to-dataset mapping, feasibility assessment, contact information for data access

G.6.3 Proposed Research Studies

Multi-Modal Hypothesis Testing Study. A comprehensive research proposal (integrated into Chapter 34) testing 5 core predictions with n=72 participants (36 ME/CFS + 36 controls) over 3 years. See Section 34.1 for full study protocol.

Budget: \$2.15M total

Funding targets: NIH R01, Solve M.E. Initiative, Open Medicine Foundation

Full proposal location: content-staging/research-proposal-selective-dysfunction.md

Review Article Outline. A 9-section outline for a comprehensive review article presenting the Selective Energy Dysfunction Hypothesis to the ME/CFS research community. Target journals: *Frontiers in Neurology*, *Journal of Translational Medicine*.

Location: content-staging/review-article-outline.md

Length: 8,000–10,000 words with 7 figures, 7 tables, 150–200 references

Key sections: Evidence review (preserved vs. impaired processes), mechanistic models, testable predictions, clinical implications, research agenda

G.6.4 Treatment Translation

Brain-Centric Treatment Protocol. [PLANNED] An evidence-based treatment protocol translating the Selective Energy Dysfunction Hypothesis into clinical practice. All recommendations are **PRELIMINARY** and require physician review before implementation.

Location: content-staging/treatment-protocol-brain-centric.md (not yet created)

Core intervention categories:

1. **Brain energy support:** MCT oil (MODERATE evidence), CoQ10/ubiquinol (MODERATE), creatine (MODERATE-emerging), D-ribose (WEAK)
2. **CNS demand reduction:** Heart rate-guided pacing, cognitive energy budgeting, sensory load reduction
3. **Pharmacological CNS bypass:** Midodrine (MODERATE), fludrocortisone (MODERATE), LDN (MODERATE), LDA (WEAK-theoretical)
4. **Clinical decision algorithm:** Foundation → first-line → second-line → third-line with clear response criteria

Evidence grading: Every intervention labeled as Strong/Moderate/Weak/Theoretical with supporting citations

Safety: Comprehensive drug interaction table, red flags, contraindications included

G.6.5 Research Community Access

All materials in content-staging/ are available for:

- Patient advocacy organizations (for survey distribution and protocol testing)
- ME/CFS researchers (for collaboration on dataset analysis or study implementation)
- Clinicians (for evidence-based protocol adaptation)
- Medical students/trainees (for hypothesis-driven research education)

Contact for collaboration. [To be determined based on institutional affiliation]

H Annotated Bibliography of ME/CFS Literature

This appendix provides a comprehensive annotated bibliography of scientific literature on Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). Sources are organized by research domain and include full identifying information where available.

H.1 Primary Research: NIH Deep Phenotyping Study

H.1.1 Walitt et al. 2024 — The Foundational Deep Phenotyping Study

Full Citation: Walitt B, Singh K, LaMunio SR, et al. Deep phenotyping of post-infectious myalgic encephalomyelitis/chronic fatigue syndrome. *Nature Communications*. 2024;15(1):907.

DOI: [10.1038/s41467-024-45107-3](https://doi.org/10.1038/s41467-024-45107-3)

PMID: 38383456

PMCID: PMC10881493

Published: February 21, 2024

Study Design: Cross-sectional deep phenotyping study

Sample Size: 17 PI-ME/CFS patients, 21 matched healthy controls

Key Findings:

- Altered effort preference rather than physical or central fatigue (OR=1.65, $p=0.04$)
- Decreased brain activation in right temporal-parietal junction during motor tasks
- CSF catechol abnormalities: decreased DOPA ($p=0.021$), DOPAC ($p=0.025$), DHPG ($p=0.006$)
- Reduced peak VO_2 on cardiopulmonary exercise testing ($p=0.004$)
- Chronotropic incompetence (5/8 PI-ME/CFS vs 1/9 controls, $p=0.03$)
- B-cell abnormalities: increased naïve B-cells ($p=0.037$), decreased switched memory B-cells ($p=0.008$)
- Sex-specific gene expression differences with <5% overlap between sexes

Conclusion: ME/CFS appears to be a centrally mediated disorder characterized by altered effort preference, potentially associated with central catecholamine dysregulation.

Limitations: Small sample size (80% power only detects effects ≥ 0.94 SD); cross-sectional design; recruitment terminated due to COVID-19 pandemic.

H.2 Diagnostic Criteria and Clinical Guidelines

H.2.1 Institute of Medicine (IOM) 2015 Criteria

Full Citation: Institute of Medicine (US) Committee on the Diagnostic Criteria for Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Beyond Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: Redefining an Illness*. Washington, DC: National Academies Press; 2015.

URL: <https://www.cdc.gov/me-cfs/hcp/diagnosis/iom-2015-diagnostic-criteria-1.html>

ISBN: 978-0-309-31689-7

Key Requirements:

- Three required symptoms: (1) substantial reduction in functioning with fatigue ≥ 6 months, (2) post-exertional malaise, (3) unrefreshing sleep
- Plus at least one of: cognitive impairment OR orthostatic intolerance
- Symptoms must be present $\geq 50\%$ of the time with moderate-to-severe intensity

Significance: Proposed renaming to Systemic Exertion Intolerance Disease (SEID); currently used by CDC.

H.2.2 NICE 2021 Guidelines (NG206)

Full Citation: National Institute for Health and Care Excellence. Myalgic encephalomyelitis (or encephalopathy)/chronic fatigue syndrome: diagnosis and management. NICE guideline [NG206]. London: NICE; 2021.

URL: <https://www.nice.org.uk/guidance/ng206>

Published: October 29, 2021

Key Changes from 2007 Guideline:

- All four core symptoms required: debilitating fatiguability, PEM, unrefreshing sleep, cognitive difficulties
- Symptoms must persist ≥ 3 months (suspected from 6 weeks in adults, 4 weeks in children)
- Graded Exercise Therapy (GET) **no longer recommended**
- CBT not considered a treatment for ME/CFS itself
- Recognition of PEM as the cardinal symptom

Adoption: Endorsed in Northern Ireland (2022); default guidance in Scotland (2025).

H.2.3 Canadian Consensus Criteria (2003)

Full Citation: Carruthers BM, Jain AK, De Meirleir KL, et al. Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: Clinical Working Case Definition, Diagnostic and Treatment Protocols. *Journal of Chronic Fatigue Syndrome*. 2003;11(1):7–115.

DOI: [10.1300/J092v11n01_02](https://doi.org/10.1300/J092v11n01_02)

Significance: First criteria to require PEM; more restrictive than Fukuda 1994; widely used in research.

H.2.4 Fukuda et al. 1994 (CDC Criteria)

Full Citation: Fukuda K, Straus SE, Hickie I, Sharpe MC, Dobbins JG, Komaroff A. The chronic fatigue syndrome: a comprehensive approach to its definition and study. *Annals of Internal Medicine*. 1994;121(12):953–959.

DOI: [10.7326/0003-4819-121-12-199412150-00009](https://doi.org/10.7326/0003-4819-121-12-199412150-00009)

PMID: 7978722

Significance: Most widely used research criteria historically; criticized for being too broad.

H.3 Institutional Clinical Guidelines

H.3.1 MedUni Wien (2024) — Care for ME/CFS Praxisleitfaden

OG ME/CFS and MedUni Wien. *Care for ME/CFS: Praxisleitfaden*. 2024. DOI: [10.5281/zenodo.12091631](https://doi.org/10.5281/zenodo.12091631)

Key Findings: Practice guide developed by Medical University of Vienna and Austrian Society for ME/CFS based on PPIE (Patient & Public Involvement and Engagement) methodology. Synthesizes data from 687 ME/CFS patients in D-A-CH region (Germany-Austria-Switzerland) via CCCFS questionnaire, plus qualitative surveys from 221 respondents and expert interviews.

Demographic findings: 84% female, 15.6% male; 70% developed ME/CFS before age 40; average diagnostic delay of 5 years. 65% moderate severity, 18% severe/very severe. 65% not working or retired (vs. 86% employed pre-illness).

Treatment efficacy data (from CCCFS survey):

- **Most effective:** Medications targeting comorbidities (MCAS, PoTS, immune deficiency) with 24–48% reporting phase-wise or sustained improvement
- **Low efficacy:** Analgesics (60–71% no improvement), antidepressants (67–77% no improvement)
- **Key principle:** Individual titration essential; no standard dosing fits all ME/CFS patients

Care structure recommendations:

- Specialized interdisciplinary clinics required (none exist in Austria/Switzerland)
- Telemedicine essential for moderate/severe patients
- Home visits necessary for severe/very severe patients
- Case management across health/social systems
- Infection control critical (FFP2 masks, air filters, spacing)

Relevance: First comprehensive institutional guideline from major European academic medical center integrating patient-reported outcomes with clinical expertise. Provides evidence for treatment prioritization (target comorbidities first) and care delivery models. Diagnostic toolbox (Canadian Consensus Criteria, Bell Scale, FUNCAP55, DSQ-PEM) provides standardized assessment framework. Particularly valuable for understanding ME/CFS presentation and needs in German-speaking healthcare contexts.

Certainty Assessment:

- **Quality:** High (institutional guideline, academic medical center, PPIE methodology)
- **Sample:** n=687 (CCCFS survey), n=221 (qualitative), n=8 (expert interviews)
- **Currency:** Very current (June 2024 publication)
- **Limitations:** Austria-specific healthcare context; CCCFS survey limited to diagnosed patients (selection bias); cross-sectional design; treatment data relies on patient self-report without standardized outcome measures

H.3.2 MedUni Wien (2025) — Indikations-Medikamentenliste für PAIS und ME/CFS

Referenzzentrum Postvirale Syndrome. *Indikations-Medikamentenliste PAIS und ME/CFS*. MedUni Wien Clinical Guideline. 2025. URL: <https://www.meduniwien.ac.at/web/referenzzentrum-postvirale-syndrome/>

Key Findings: Official medication list for ME/CFS and post-acute infection syndromes (PAIS) covered by Austrian health insurance (ÖGK, BVAEB, SVS) as of February 21, 2025. All medications are off-label for ME/CFS indication.

Medication categories:

1. **Sleep disturbances:** Melatonin (sustained-release) 2–4mg
2. **Mast cell activation (MCAS):** H1/H2 blockers, ketotifen, cromolyn sodium
3. **PoTS tachycardia:** Cardioselective beta-blockers (nebivolol), ivabradine
4. **Orthostatic intolerance:** Pyridostigmine 10–60mg, midodrine, fludrocortisone
5. **Endothelial dysfunction/PEM prevention:** Statins (atorvastatin 10mg), magnesium, diosmin
6. **Microthrombi/circulation:** Aspirin 50mg, sulodexide, clopidogrel, ginkgo 80mg
7. **Cognitive dysfunction (neuroinflammation):** LDN 0.5–5mg, LDA 0.25–2mg, fluvoxamine, guanfacin + NAC

Dosing principles emphasized:

- Start lowest dose, titrate slowly
- Discontinue if adverse effects
- ME/CFS patients frequently report medication intolerances

- Trial reduction/discontinuation over time
- No standard schema fits all patients

Relevance: First official institutional medication list for ME/CFS with insurance coverage in a national healthcare system. Validates off-label use of medications commonly prescribed in ME/CFS community but lacking formal guidelines. Particularly significant for: (1) institutionalizing LDN and LDA for cognitive dysfunction, (2) recognizing MCAS and PoTS as core ME/CFS comorbidities requiring treatment, (3) addressing endothelial dysfunction/microthrombi hypothesis with antiplatelet agents. Provides template for systematic approach to symptom-targeted pharmacotherapy when disease-modifying treatments are unavailable.

Certainty Assessment:

- **Quality:** High (institutional clinical guideline, insurance-endorsed)
- **Evidence base:** Mix of published literature, clinical experience, and Praxisleitfaden patient survey data
- **Currency:** Very current (February 2025)
- **Regional applicability:** Austria-specific insurance coverage; medications available internationally but coverage varies
- **Limitations:** All off-label use; requires thorough informed consent; compounding pharmacy needed for LDN/LDA; Schellong/tilt-table testing required for PoTS medications

H.4 Systematic Reviews and Meta-Analyses

H.4.1 Prevalence and Epidemiology

Full Citation: Lim E-J, Ahn Y-C, Jang E-S, Lee S-W, Lee S-H, Son C-G. Systematic review and meta-analysis of the prevalence of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). *Journal of Translational Medicine*. 2020;18(1):100.

DOI: [10.1186/s12967-020-02269-0](https://doi.org/10.1186/s12967-020-02269-0)

PMID: 32093722

PMCID: PMC7038594

Key Findings: Pooled prevalence 0.89% (95% CI: 0.60–1.33%); women 1.36% vs men 0.86%; children/adolescents 0.55%.

Full Citation: Centers for Disease Control and Prevention. Myalgic Encephalomyelitis/Chronic Fatigue Syndrome in Adults: United States, 2021–2022. NCHS Data Brief No. 488. Hyattsville, MD: National Center for Health Statistics; 2023.

URL: <https://www.cdc.gov/nchs/products/databriefs/db488.htm>

Key Findings: 1.3% of US adults have ME/CFS; prevalence increases with age through 60–69 years; 84–91% remain undiagnosed.

H.4.2 Cognitive Impairment

Full Citation: Sebaiti MA, Hainselin M, Gounden Y, et al. Systematic review and meta-analysis of cognitive impairment in myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). *Scientific Reports*. 2022;12(1):2157.

DOI: [10.1038/s41598-021-04764-w](https://doi.org/10.1038/s41598-021-04764-w)

PMID: 35145174

Key Findings: Large effect size for verbal working memory deficits; no significant difference in visual working memory.

H.4.3 Long COVID and ME/CFS Overlap

Full Citation: Wong TL, Weitzer DJ. Long COVID and Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS)—A Systematic Review and Comparison of Clinical Presentation and Symptomatology. *Medicina*. 2021;57(5):418.

DOI: [10.3390/medicina57050418](https://doi.org/10.3390/medicina57050418)

PMCID: PMC8145228

Full Citation: The persistence of myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) after SARS-CoV-2 infection: A systematic review and meta-analysis. *Journal of Infection*. 2024;89(4):101231.

DOI: [10.1016/j.jinf.2024.106231](https://doi.org/10.1016/j.jinf.2024.106231)

PMID: 39353473

Key Findings: Approximately half of Long COVID patients fulfill ME/CFS diagnostic criteria.

H.4.4 Sleep Abnormalities

Full Citation: Baig S, Engelbrecht K, Engelbrecht F, et al. Objective sleep measures in chronic fatigue syndrome patients: A systematic review and meta-analysis. *Sleep Medicine Reviews*. 2023;69:101775.

DOI: [10.1016/j.smrv.2023.101775](https://doi.org/10.1016/j.smrv.2023.101775)

PMID: 37116254

PMCID: PMC10281648

Sample: 24 studies; 801 adults (426 ME/CFS, 375 controls); 477 adolescents

Key Findings: Longer sleep latency, reduced sleep efficiency, longer REM latency, altered sleep microstructure.

Full Citation: Maksoud R, du Preez S, Eaton-Fitch N, et al. Systematic Review of Sleep Characteristics in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Healthcare*. 2021;9(5):568.

DOI: [10.3390/healthcare9050568](https://doi.org/10.3390/healthcare9050568)

PMCID: PMC8150292

H.4.5 Evidence Mapping

Full Citation: Toogood PL, Clauw DJ, Engel CC, et al. Recent research in myalgic encephalomyelitis/chronic fatigue syndrome: an evidence map. *BMC Medicine*. 2025;23(1):134.

PMCID: PMC11973615

Scope: Mapping ME/CFS evidence from 2018–2023.

H.5 Pathophysiology: Immune Dysfunction

H.5.1 Autoantibodies and G-Protein Coupled Receptors

Full Citation: Wirth K, Scheibenbogen C. Autoantibodies to Vasoregulative G-Protein-Coupled Receptors Correlate with Symptom Severity, Autonomic Dysfunction and Disability in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Journal of Clinical Medicine*. 2021;10(16):3675.

DOI: [10.3390/jcm10163675](https://doi.org/10.3390/jcm10163675)

PMID: 34441971

PMCID: PMC8397061

Key Findings: Anti- β 2, M3, M4 receptor antibodies elevated; correlate with fatigue and muscle pain severity.

Full Citation: Müller JA, Subburayalu J, Winkler F, et al. Dysregulated autoantibodies targeting vaso- and immunoregulatory receptors in Post COVID Syndrome correlate with symptom severity. *Frontiers in Immunology*. 2022;13:981532.

DOI: [10.3389/fimmu.2022.981532](https://doi.org/10.3389/fimmu.2022.981532)

Full Citation: Stein E, Heindrich C, Wittke K, et al. Efficacy of repeated immunoadsorption in patients with post-COVID myalgic encephalomyelitis/chronic fatigue syndrome and elevated β 2-adrenergic receptor autoantibodies: a prospective cohort study. *The Lancet Regional Health – Europe*. 2025;48:101161.

DOI: [10.1016/j.lanepe.2024.101161](https://doi.org/10.1016/j.lanepe.2024.101161)

PMID: 39759581

Published: February 2025

Study Design: Prospective cohort study

Key Findings: Repeated immunoadsorption treatment in post-COVID ME/CFS patients with elevated β 2-adrenergic receptor autoantibodies showed efficacy in improving symptoms. Provides evidence for autoantibody-targeted therapy as a therapeutic approach.

Relevance: First prospective cohort demonstrating therapeutic benefit of removing GPCR autoantibodies. Validates autoantibodies as pathogenic rather than epiphenomenal. Opens therapeutic avenue for subset of ME/CFS patients with elevated autoantibody levels.

Certainty: High (prospective design, published in *Lancet Regional Health*, targeted patient selection based on biomarker).

Full Citation: Loebel M, Grabowski P, Heidecke H, et al. Antibodies to beta adrenergic and muscarinic cholinergic receptors in patients with Chronic Fatigue Syndrome. *Brain Behav Immun*. 2016;52:32–39.

DOI: [10.1016/j.bbi.2015.09.013](https://doi.org/10.1016/j.bbi.2015.09.013)

PMID: 26399744

Published: February 2016

Study Design: Case-control study with autoantibody profiling

Key Findings: Original landmark study identifying elevated autoantibodies against β -adrenergic receptors (β_1 , β_2) and muscarinic acetylcholine receptors (M3, M4) in ME/CFS patients. Established foundation for GPCR autoantibody hypothesis in ME/CFS pathophysiology.

Relevance: First systematic documentation of GPCR autoantibodies in ME/CFS. These receptors regulate cardiovascular function, autonomic nervous system, and energy metabolism—providing mechanistic link to core ME/CFS symptoms including orthostatic intolerance, cognitive dysfunction, and autonomic dysregulation.

Certainty: High (published in *Brain Behav Immun*, replicated in multiple subsequent studies including Sotzny 2021 and Bynke 2020).

Full Citation: Freitag H, Szklarski M, Lorenz S, Sotzny F, et al. Autoantibodies to Vasoregulative G-Protein-Coupled Receptors Correlate with Symptom Severity, Autonomic Dysfunction and Disability in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *J Clin Med*. 2021;10(16):3675.

DOI: [10.3390/jcm10163675](https://doi.org/10.3390/jcm10163675)

PMID: 34441971

Published: August 2021

Study Design: Cross-sectional correlation study

Key Findings: Demonstrated dose-response relationship between GPCR autoantibody levels and symptom severity, autonomic dysfunction severity, and disability scores. Autoantibodies against β_2 -adrenergic, M3, and M4 receptors showed strongest correlations.

Relevance: Critical evidence that autoantibodies are not merely present but functionally relevant—their levels predict clinical severity. Supports autoantibodies as biomarker for patient stratification and potential therapeutic target selection.

Certainty: High (symptom correlation strengthens causal inference, published in peer-reviewed journal, consistent with mechanistic studies).

Full Citation: Bynke A, Julin P, Gottfries CG, Heidecke H, Scheibenbogen C, Bergquist J. Autoantibodies to beta-adrenergic and muscarinic cholinergic receptors in Myalgic Encephalomyelitis (ME) patients—A validation study in plasma and cerebrospinal fluid from two Swedish cohorts. *Brain Behav Immun Health*. 2020;7:100107.

DOI: [10.1016/j.bbih.2020.100107](https://doi.org/10.1016/j.bbih.2020.100107)

Published: August 2020

Study Design: Validation study in independent Swedish cohorts with CSF analysis

Key Findings: Validated Loebel 2016 findings in two independent Swedish ME/CFS cohorts. Importantly, detected GPCR autoantibodies in cerebrospinal fluid in addition to plasma,

demonstrating central nervous system exposure to autoantibodies.

Relevance: Independent international validation strengthens evidence for GPCR autoantibodies in ME/CFS. CSF detection particularly important—demonstrates autoantibodies can access CNS compartment, providing mechanism for neurological and cognitive symptoms.

Certainty: High (independent replication in separate geographic population, CSF analysis adds mechanistic insight).

Full Citation: Hohberger B, et al. Case Report: Neutralization of Autoantibodies Targeting G-Protein-Coupled Receptors Improves Capillary Impairment and Fatigue Symptoms After COVID-19 Infection. *Front Med.* 2021;8:754667.

DOI: [10.3389/fmed.2021.754667](https://doi.org/10.3389/fmed.2021.754667)

PMID: 34869451

Published: November 2021

Study Design: Case report with BC007 aptamer treatment

Key Findings: BC007 DNA aptamer neutralized GPCR autoantibodies in Long COVID patient, resulting in improved capillary blood flow (documented by nailfold capillaroscopy) and reduced fatigue symptoms. Provided proof-of-concept for targeted autoantibody neutralization.

Relevance: First demonstration that neutralizing GPCR autoantibodies improves objective vascular parameters and symptoms. BC007 represents novel therapeutic approach distinct from immunoadsorption. Microcirculation improvement suggests mechanism for cerebral hypoperfusion in ME/CFS.

Certainty: Medium (single case report limits generalizability; objective capillary measurements strengthen evidence; awaits controlled trials).

Full Citation: Hackel A, Sotzny F, Mennenga E, et al. Autoantibody-Driven Monocyte Dysfunction in Post-COVID Syndrome with Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *medRxiv [Preprint]*. 2025.

DOI: [10.1101/2025.01.09.25320264](https://doi.org/10.1101/2025.01.09.25320264)

Published: January 2025

Study Design: In vitro mechanistic study with patient-derived autoantibodies

Key Findings: GPCR autoantibodies from post-COVID ME/CFS patients reprogram monocyte function, altering cytokine secretion and inflammatory responses. Demonstrates functional mechanism by which autoantibodies could drive immune dysregulation beyond direct receptor effects.

Relevance: Extends GPCR autoantibody hypothesis beyond autonomic/vascular effects to include immune cell reprogramming. Provides mechanistic link between autoantibodies and immune dysfunction documented in ME/CFS. Monocyte dysfunction could amplify inflammation and contribute to chronic immune activation.

Certainty: Medium-High (preprint pending peer review; mechanistic in vitro evidence is robust; requires in vivo validation).

H.5.2 TRPM3 Ion Channel Dysfunction

Full Citation: Sasso E, Smith P, Marshall-Gradisnik S, et al. Multi-site validation of TRPM3 ion channel dysfunction in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Frontiers in Medicine*. 2026.

DOI: [10.3389/fmed.2025.1703924](https://doi.org/10.3389/fmed.2025.1703924)

Published: January 13, 2026

Institution: Griffith University, National Centre for Neuroimmunology and Emerging Diseases (NCNED)

Study Design: Multi-site validation study using gold-standard techniques

Key Findings:

- TRPM3 ion channel (a calcium-permeable channel in immune cells) functions abnormally in ME/CFS patients compared to healthy controls
- Defect reproducibly observed across independent laboratories over 4,000 km apart (Gold Coast and Perth, Australia)
- Faulty ion channels act like “stuck doors,” preventing cells from receiving calcium needed for immune function

Significance: Provides robust, multi-site validated evidence of measurable cellular abnormalities in ME/CFS. Supports development of diagnostic tests and identifies potential therapeutic targets. Offers greater recognition of ME/CFS as a legitimate medical condition with objective biological markers.

Lead Researchers: Professor Sonya Marshall-Gradisnik (Director), Dr. Etianne Sasso (Lead Author), Dr. Peter Smith

H.5.3 Immune Exhaustion and Chronic Activation

Full Citation: Immune exhaustion in ME/CFS and long COVID. *JCI Insight*. 2024;9(19):e183810.

DOI: [10.1172/jci.insight.183810](https://doi.org/10.1172/jci.insight.183810)

H.5.4 Cytokine Biomarkers and Immune Signatures

Hornig et al. 2015 — Duration-Dependent Cytokine Signatures [334]

Key Findings: This landmark study in *Science Advances* identified distinct immune signatures in ME/CFS that vary by disease duration. Among 298 ME/CFS patients and 348 controls, early-stage patients (<3 years) showed prominent activation of both pro- and anti-inflammatory cytokines, including elevated IL-1 α , IL-8, IL-10, IL-12p40, IL-17F, IFN- γ , CXCL1, CXCL9, and IL-5. In stark contrast, patients with longer disease duration (>3 years) had normalized cytokine levels. A 17-cytokine panel distinguished early ME/CFS from controls with high accuracy.

Relevance: Provides the strongest evidence to date that ME/CFS immunopathology evolves over time, potentially from initial immune activation to exhaustion or adaptation. This duration-dependent pattern explains heterogeneity in previous cytokine studies that failed to stratify by illness duration and suggests therapeutic windows where early intervention may be more effective.

Certainty Assessment:

- **Quality:** High (published in *Science Advances*, large sample size, rigorous methodology)
- **Sample:** n=646 total (298 ME/CFS, 348 controls)
- **Replication:** Partially replicated in Montoya 2017 and Che 2025
- **Limitations:** Cross-sectional design cannot track individual progression; mechanism of cytokine normalization unclear

Montoya et al. 2017 — Cytokine-Severity Correlation [335]

Key Findings: This *PNAS* study demonstrated dose-response relationships between cytokines and symptom severity. Although only two cytokines differed overall between patients and controls (TGF- β higher, resistin lower), 17 cytokines showed significant upward linear trends correlating with disease severity. Thirteen of these 17 are proinflammatory: CCL11, CXCL1, CXCL10, IFN- γ , IL-4, IL-5, IL-7, IL-12p70, IL-13, IL-17F, G-CSF, GM-CSF, and TGF- α . CXCL9 inversely correlated with fatigue duration, consistent with Hornig 2015's duration-dependent findings.

Relevance: Provides evidence that immune activation tracks with symptom burden. The dose-response relationship (rather than binary patient-control comparison) suggests cytokine profiling could stratify patients for clinical trials and identify those likely to benefit from immunomodulatory therapies. Complements Hornig 2015 by focusing on severity rather than duration.

Certainty Assessment:

- **Quality:** High (published in *PNAS*, large sample, Stanford affiliation)
- **Sample:** n=584 (192 ME/CFS, 392 controls)
- **Replication:** Partially replicated in Che 2025
- **Limitations:** Cross-sectional; cannot determine causality; severity assessment subjective

Che et al. 2025 — Sex-Specific Immune Dysregulation [91]

Key Findings: Multi-omics study from the Walitt/Lipkin group demonstrated exaggerated innate immune responses to microbial stimulation in ME/CFS, with IL-6 and other proinflammatory cytokines elevated before and markedly increased after exercise. Critically, hyperinflammatory responses were amplified in women over 45 years with diminished estradiol levels, suggesting sex hormone-immune interactions. The study also identified impaired energy production (TCA cycle dysfunction, fatty acid oxidation defects) that worsened post-exercise.

Relevance: Extends previous cytokine findings to reveal sex- and age-specific patterns. The estradiol-cytokine relationship provides mechanistic insight into female predominance of ME/CFS and suggests potential therapeutic interventions (estrogen supplementation for older women). Integrates immune and metabolic dysfunction, supporting multi-system pathophysiology model.

Certainty Assessment:

- **Quality:** High (Nature portfolio journal, rigorous multi-omics approach)
- **Sample:** Specific n not provided in abstract
- **Replication:** Confirms and extends Hornig/Montoya cytokine findings
- **Limitations:** Sex-hormone mechanism needs further validation

Giloteaux et al. 2023 — IL-2 in Extracellular Vesicles [\[336\]](#)

Key Findings: Novel study examining cytokine content in extracellular vesicles (EVs) rather than free plasma. IL-2 was significantly elevated in ME/CFS patient EVs. Proinflammatory cytokines CSF2 and TNF α correlated with physical and fatigue symptom severity. EVs represent cell-to-cell signaling mechanism and may better reflect active immune communication.

Relevance: Identifies IL-2 as potentially important cytokine in ME/CFS pathophysiology. Notably, Hunter 2025 independently identified IL-2 pathway using epigenetic methods, providing convergent evidence from different methodologies. EV-based analysis may reveal immune signals missed by conventional plasma assays.

Certainty Assessment:

- **Quality:** Medium-High (novel methodology, peer-reviewed)
- **Sample:** n=98 (49 ME/CFS, 49 controls)
- **Replication:** IL-2 finding supported by Hunter 2025; EV method needs replication
- **Limitations:** Single study with novel methodology; EV assays less standardized than plasma

Hunter et al. 2025 — Epigenetic Biomarkers and IL-2 Pathway [337]

Key Findings: Developed blood-based diagnostic test using EpiSwitch® technology identifying 200 chromosome conformation markers that distinguish ME/CFS from controls with 92% sensitivity and 98% specificity. Pathway analysis revealed involvement of IL-2, TNF α , toll-like receptor signaling, and JAK/STAT mechanisms. IL-2 identified as shared pathway with existing therapies (Rituximab, glatiramer acetate).

Relevance: Provides epigenetic validation of immune pathways identified by cytokine studies. High diagnostic specificity (98%) suggests potential clinical utility. IL-2 pathway finding converges with Giloteaux 2023, supporting IL-2 as therapeutic target. Study focused on severely affected patients.

Certainty Assessment:

- **Quality:** Medium-High (peer-reviewed, high diagnostic accuracy)
- **Sample:** n=108 (47 ME/CFS, 61 controls)
- **Replication:** Single study; proprietary technology limits independent validation
- **Limitations:** Severe patients only; EpiSwitch technology not widely available; needs independent cohort validation

H.5.5 Natural Killer Cell Dysfunction

Eaton-Fitch et al. 2019 — Systematic Review of NK Cell Function [3]

Key Findings: This systematic review examined 17 observational case-control studies published between 1994–2018. Impaired NK cell cytotoxicity remained the most consistent immunological abnormality across all publications. Of 11 studies investigating NK cytotoxicity, 7 reported significantly reduced killing capacity in ME/CFS patients compared to healthy controls. The review concluded that impaired NK cell cytotoxicity is “a reliable and appropriate cellular model for continued research in ME/CFS patients.”

Relevance: Provides high-quality systematic evidence that NK cell dysfunction is one of the most replicated findings in ME/CFS research, spanning over two decades of independent studies. Establishes NK cytotoxicity as a potential biomarker and therapeutic target.

Certainty Assessment:

- **Quality:** High (systematic review published in Systematic Reviews journal)
- **Sample:** 17 independent case-control studies reviewed
- **Replication:** Highly replicated (7 of 11 studies confirmed reduced NK cytotoxicity)
- **Limitations:** Heterogeneity in measurement methods across studies; mechanisms remain unclear

Maier et al. 2005 — Perforin Deficiency in CFS NK Cells [\[321\]](#)

Key Findings: This mechanistic study demonstrated that CFS patients have 45% reduction in NK cell perforin content (3,320 vs 6,051 rMol/cell, $p = 0.01$) compared to healthy controls. Significant correlation was found between NK cell activity and intracellular perforin levels across all participants. Additionally, evidence suggested reduced perforin in CD8+ T cells, providing the first indication of T cell-associated cytotoxic deficit in CFS.

Relevance: Provides a molecular mechanism explaining why NK cells in CFS have impaired cytotoxicity: insufficient perforin prevents effective target cell killing even when NK cells successfully recognize their targets. Links NK and T cell dysfunction through shared cytotoxic granule deficiency.

Certainty Assessment:

- **Quality:** High (published in Clinical and Experimental Immunology, direct molecular measurement)
- **Sample:** Not specified in abstract
- **Replication:** Single study; findings consistent with broader NK dysfunction literature
- **Limitations:** Mechanism of perforin deficiency unclear; needs replication in larger cohorts

Brenu et al. 2011 — Comprehensive Immune Profiling (n=95) [\[322\]](#)

Key Findings: Large comprehensive study (n=95 CFS/ME patients, n=50 controls) examining multiple immune parameters. Found significantly reduced NK and CD8+ T cell cytotoxicity, decreased CD56bright NK cell populations, and paradoxically low granzyme A/K expression despite elevated perforin levels. Cytokine analysis revealed elevated IL-10 (anti-inflammatory), IFN- γ , and TNF- α (pro-inflammatory), suggesting simultaneous activation and suppression. Increased CD4+CD25+ regulatory T cells and FoxP3 expression were also observed.

Relevance: One of the largest comprehensive immune profiling studies in ME/CFS. The paradoxical low granzymes with normal/elevated perforin refines the Maher 2005 findings, suggesting granule composition defects rather than simple perforin deficiency. Demonstrates that immune dysfunction extends across multiple cell types and pathways. Authors proposed these abnormalities as potential diagnostic biomarkers.

Certainty Assessment:

- **Quality:** High (large sample, published in Journal of Translational Medicine, comprehensive methodology)
- **Sample:** n=145 total (95 CFS/ME, 50 controls)
- **Replication:** Confirms NK/T cell dysfunction from other studies; granzyme findings novel
- **Limitations:** Cross-sectional; cannot determine causality; heterogeneous patient population

H.5.6 T Cell Metabolic Dysfunction

Mandarano et al. 2020 — T Cell Bioenergetic Deficits [296]

Key Findings: First comprehensive metabolic analysis of T cells in ME/CFS (n=53 patients, n=45 controls). CD8+ T cells showed reduced mitochondrial membrane potential, impaired glycolysis at rest, and failed metabolic reprogramming following activation. Healthy T cells switch from oxidative phosphorylation to glycolysis when activated (Warburg effect), but ME/CFS CD8+ T cells cannot make this transition effectively. CD4+ T cells also demonstrated reduced baseline glycolysis. ME/CFS patients exhibited unique plasma cytokine-metabolism correlations differing from healthy controls.

Relevance: Bridges immune dysfunction and bioenergetic impairment chapters, demonstrating that metabolic deficits extend to immune cells. Provides mechanistic explanation for reduced CD8+ cytotoxic function observed in previous studies (Brenu 2011, Maher 2005): insufficient ATP to sustain degranulation and target killing. Explains why immune activation may worsen fatigue—metabolically compromised immune cells compete with other tissues for limited ATP. Published in top-tier Journal of Clinical Investigation.

Certainty Assessment:

- **Quality:** Very High (JCI publication, large sample, direct metabolic measurements)
- **Sample:** n=98 total (53 ME/CFS, 45 controls)
- **Replication:** Single study; novel methodology
- **Limitations:** Cross-sectional; mechanism linking mitochondrial dysfunction to immune dysfunction unclear

H.5.7 Neutrophil Dysfunction

Kennedy et al. 2004 — Increased Neutrophil Apoptosis [324]

Key Findings: CFS patients (n=47) demonstrated increased neutrophil apoptosis compared to controls (n=34): 37.4% vs 22.8% annexin V binding ($p = 0.001$), elevated TNFRI death receptor expression ($p = 0.004$), and raised active TGF- β 1 concentrations ($p < 0.005$). Higher apoptosis resulted in lower numbers of viable neutrophils. Authors concluded this represents “an underlying, detectable abnormality in the behaviour of their immune cells, consistent with an activated inflammatory process.”

Relevance: Demonstrates that immune dysfunction in CFS extends beyond lymphocytes to innate immune cells (neutrophils). Increased apoptosis suggests accelerated neutrophil turnover and may impair antimicrobial defense. Links neutrophil dysfunction to elevated TNF- α found in cytokine studies, providing mechanistic connection. Supports concept of “activated but exhausted” immune phenotype.

Certainty Assessment:

- **Quality:** Moderate-High (published in Journal of Clinical Pathology, clear statistical significance)
- **Sample:** n=81 total (47 CFS, 34 controls)
- **Replication:** Single study; needs independent replication
- **Limitations:** Functional consequences of increased apoptosis not directly measured; mechanism unclear

H.5.8 Autoantibodies: Historical Context

Nishikai 2007 — ANA Prevalence and 68/48 kDa Autoantibodies [330]

Key Findings: Review of Nishikai’s research program on autoantibodies in CFS. Antinuclear antibodies (ANA) detected in 15–25% of CFS patients using indirect immunofluorescence with HEp-2 cells, with generally low titers and heterogeneous patterns. Specific autoantibodies to 68/48 kDa protein found in 13.2% of CFS patients and 15.6% of fibromyalgia patients, compared to 0% of healthy controls ($p < 0.05$). These autoantibodies associated with hypersomnia and difficulty concentrating.

Relevance: Represents pioneering early work (1990s–2000s) establishing that a subset of CFS patients have autoimmune markers, though the majority (75–85%) are ANA-negative. Preceded more sophisticated GPCR autoantibody research (Scheibenbogen, Stein) by nearly two decades. The 68/48 kDa autoantibody-cognitive symptom association suggests autoantibodies may contribute to specific symptom subsets, supporting patient heterogeneity and potential subgroup stratification.

Certainty Assessment:

- **Quality:** Moderate (multiple studies by same group, peer-reviewed)
- **Sample:** Various studies; 2001 study had n=114 CFS patients
- **Replication:** Limited independent replication; findings preceded modern GPCR autoantibody era
- **Limitations:** Less specific autoantibody assays than current methods; functional significance of ANA unclear; 68/48 kDa target not fully characterized

H.5.9 Comprehensive Immune Reviews

DOI: [10.3389/fneur.2022.877772](https://doi.org/10.3389/fneur.2022.877772)

H.6.2 Neuroimaging Reviews

Full Citation: Shan ZY, Barnden LR, Kwiatek RA, Bhuta S, Groszmann M, Blumbergs PC. Neuroimaging characteristics of myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS): a systematic review. *Journal of Translational Medicine*. 2020;18(1):335.

DOI: [10.1186/s12967-020-02506-6](https://doi.org/10.1186/s12967-020-02506-6)

Key Findings: Evidence for structural, functional, and metabolic brain abnormalities; hypoperfusion in multiple regions.

Full Citation: Metabolic neuroimaging of myalgic encephalomyelitis/chronic fatigue syndrome and Long-COVID. *Immunometabolism*. 2025;10:e00068.

DOI: [10.1097/IN9.0000000000000068](https://doi.org/10.1097/IN9.0000000000000068)

H.6.3 Brain Energy Metabolism and the Astrocyte-Neuron Lactate Shuttle

Full Citation: Kim Y, Dube SE, Park CB. Brain energy homeostasis: the evolution of the astrocyte-neuron lactate shuttle hypothesis. *Korean Journal of Physiology and Pharmacology*. 2025;29(1):1–8.

DOI: [10.4196/kjpp.24.388](https://doi.org/10.4196/kjpp.24.388)

PMID: 39725609

Key Findings: Comprehensive review documenting the evolution of the ANLS hypothesis. MCT1/MCT4 downregulation reduces neuronal lactate supply by approximately 60%. ANLS dysfunction is documented in Alzheimer's disease, ALS, epilepsy, and major depression. Recent evidence shows neurons possess more metabolic flexibility (LDHA expression) than originally assumed, refining but not invalidating the ANLS model.

Relevance: Provides the neuroscience foundation for the astrocyte energy gate hypothesis in ME/CFS. If neuroinflammation in ME/CFS causes MCT downregulation similar to other neurological conditions, this would explain CNS-specific energy failure.

Certainty: High for ANLS physiology review; moderate for disease associations (published in peer-reviewed journal, well-referenced).

Full Citation: Godlewska BR, Sylvester AL, Emir UE, et al. Brain and muscle chemistry in myalgic encephalitis/chronic fatigue syndrome (ME/CFS) and long COVID: a 7T magnetic resonance spectroscopy study. *Molecular Psychiatry*. 2025;30:5215–5226.

DOI: [10.1038/s41380-025-03108-8](https://doi.org/10.1038/s41380-025-03108-8)

Study Design: Cross-sectional, ultra-high-field (7T) MRS

Sample Size: n=24 ME/CFS, n=25 Long COVID, n=24 healthy controls

Key Findings: ME/CFS patients showed elevated brain lactate in pregenual anterior cingulate cortex (pgACC: 1.52 vs. 1.22 mM, $p = 0.003$) and dorsal ACC compared to healthy controls. ME/CFS and Long COVID demonstrated distinct neurochemical profiles despite similar clinical presentations, suggesting different underlying mechanisms.

Relevance: Provides direct evidence of brain metabolic stress in ME/CFS. Elevated lactate is consistent with impaired oxidative metabolism, potentially reflecting ANLS dysfunction, mitochondrial impairment, or hypoperfusion-driven anaerobic shift. The distinction between ME/CFS and Long COVID neurochemistry supports disease-specific mechanisms.

Certainty: Moderate-High (published in *Molecular Psychiatry*, ultra-high-field 7T MRS, adequate sample size for neuroimaging, but single-site study requiring replication).

Full Citation: Mueller C, Lin JC, Sheriff S, Maudsley AA, Younger JW. Evidence of widespread metabolite abnormalities in Myalgic encephalomyelitis/chronic fatigue syndrome: assessment with whole-brain magnetic resonance spectroscopy. *Brain Imaging and Behavior*. 2020;14(2):562–572.

DOI: [10.1007/s11682-018-0029-4](https://doi.org/10.1007/s11682-018-0029-4)

PMID: 30617782

Study Design: Case-control, whole-brain MRS

Sample Size: n=15 ME/CFS, n=15 healthy controls

Key Findings: Elevated lactate-to-creatine ratios in right insula, thalamus, and cerebellum. Brain temperature increases correlated with lactate elevations, suggesting neuroinflammation drives metabolic shifts. Also found elevated choline (abnormal phospholipid metabolism) and myo-inositol (glial marker) widespread across brain regions.

Relevance: First whole-brain MRS study in ME/CFS showing widespread rather than focal metabolite abnormalities. The co-localization of lactate elevation with temperature increases supports neuroinflammation-driven metabolic dysfunction rather than isolated mitochondrial defects.

Certainty: Moderate (small sample size n=15, but published in peer-reviewed journal with whole-brain methodology providing comprehensive coverage).

Full Citation: Syed AM, Karius AK, Ma J, Wang P-Y, Hwang PM. Mitochondrial dysfunction in myalgic encephalomyelitis/chronic fatigue syndrome. *Physiology*. 2025.

DOI: [10.1152/physiol.00056.2024](https://doi.org/10.1152/physiol.00056.2024)

Key Findings: Comprehensive review documenting elevated CSF lactate, impaired ATP synthesis, and increased glycolytic activity in ME/CFS. Phosphorus-31 MRS shows increased intracellular acidosis consistent with glycolytic shift. Brain-specific lactate elevation linked to neuroinflammation and mitochondrial dysfunction.

Relevance: Establishes the evidence base for mitochondrial dysfunction as a core pathophysiological mechanism in ME/CFS, with specific implications for brain energy metabolism.

Certainty: Moderate-High (comprehensive review in *Physiology*, synthesizes multiple lines of evidence).

Full Citation: Jang J, Kim SR, Lee JE, et al. Molecular mechanisms of neuroprotection by ketone bodies and ketogenic diet in cerebral ischemia and neurodegenerative diseases.

International Journal of Molecular Sciences. 2024;25(1):124.

DOI: [10.3390/ijms25010124](https://doi.org/10.3390/ijms25010124)

PMID: 38203294

Key Findings: Ketone bodies (BHB, acetoacetate) traverse the blood-brain barrier via MCT1, enter neurons via MCT2, and undergo oxidation in neuronal mitochondria—bypassing the astrocyte glycolysis step of the ANLS entirely. BHB enhances mitochondrial efficiency by reducing the NAD⁺/NADH ratio and increasing ATP hydrolysis energy yield.

Relevance: Provides the mechanistic rationale for ketogenic diet as a potential intervention for ANLS dysfunction in ME/CFS. If the energy gate bottleneck is at the astrocyte level, ketones offer a direct neuronal fuel source that bypasses the impaired step.

Certainty: High for ketone metabolism physiology; speculative for ME/CFS application (no ME/CFS-specific ketogenic studies cited).

H.6.4 Brainstem and Autonomic Dysfunction

Full Citation: Newton JL, Okonkwo O, Sutcliffe K, Seth A, Shin J, Jones DEJ. Symptoms of Autonomic Dysfunction in Chronic Fatigue Syndrome. *QJM: An International Journal of Medicine*. 2007;100(8):519–526.

DOI: [10.1093/qjmed/hcm057](https://doi.org/10.1093/qjmed/hcm057)

PMID: 17617647

Published: August 2007

Study Design: Cross-sectional prevalence study

Sample Size: CFS patients compared to healthy controls

Key Findings: First systematic study documenting high prevalence of autonomic symptoms in ME/CFS using the Composite Autonomic Symptom Scale (COMPASS). CFS patients showed significantly elevated autonomic symptom scores across all domains (orthostatic, vasomotor, secretomotor, gastrointestinal, bladder/bowel). Establishes autonomic dysfunction as core clinical feature of ME/CFS, not incidental finding.

Relevance: Landmark paper establishing autonomic dysfunction as integral to ME/CFS pathophysiology. COMPASS scale provides validated assessment tool. Foundation for subsequent studies on POTS prevalence and autonomic mechanisms in ME/CFS. Explains orthostatic intolerance, tachycardia, and vasomotor symptoms common to ME/CFS patients.

Certainty: High (published in *QJM*, established prevalence, validated symptom scale, replicated in subsequent studies).

Full Citation: Hoad A, Spickett G, Elliott J, Newton J. Postural Orthostatic Tachycardia Syndrome is an Under-Recognized Condition in Chronic Fatigue Syndrome. *QJM: An International Journal of Medicine*. 2008;101(12):961–965.

DOI: [10.1093/qjmed/hcn123](https://doi.org/10.1093/qjmed/hcn123)

PMID: 18805903

Published: December 2008

Study Design: Cross-sectional prevalence study with tilt table testing

Sample Size: ME/CFS patients (n varied), healthy controls

Key Findings: Formal tilt table testing in Northern CFS/ME Clinical Network patients found 27% prevalence of POTS in ME/CFS patients compared to 9% in healthy controls (approximately 3-fold increased prevalence). Authors note POTS is under-recognized and underdiagnosed in ME/CFS despite high prevalence. POTS diagnosis requires standardized tilt table protocol to detect heart rate response ≥ 30 bpm increase upon standing.

Relevance: Establishes POTS as significantly over-represented in ME/CFS population. Critical for clinical recognition and appropriate management. Suggests POTS screening (via Schellong test or tilt table) should be standard in ME/CFS evaluation. POTS comorbidity may explain subset of patients with severe orthostatic intolerance and exercise intolerance.

Certainty: High (UK clinical network study, objective testing via tilt table, published in *QJM*, replicated finding in multiple cohorts).

Full Citation: Sheldon RS, Grubb BP, Olshansky B, et al. 2015 Heart Rhythm Society Expert Consensus Statement on the Diagnosis and Treatment of Postural Tachycardia Syndrome, Inappropriate Sinus Tachycardia, and Vasovagal Syncope. *Heart Rhythm*. 2015;12(6):e41–e63.

DOI: [10.1016/j.hrthm.2015.03.029](https://doi.org/10.1016/j.hrthm.2015.03.029)

PMID: 25980576

PMCID: PMC5267948

Published: June 2015

Document Type: Multidisciplinary expert consensus statement from Heart Rhythm Society

Authors: 21 international cardiac electrophysiologists and autonomic specialists

Key Findings: Consensus definition of POTS: sustained heart rate increase ≥ 30 bpm upon standing (or ≥ 40 bpm in ages 12–19) in absence of hypovolemia or supine hypertension, occurring within 5 minutes of standing. Diagnostic criteria include either active standing or head-up tilt at 60–80°. Consensus addresses pathophysiology (neuropathic POTS, hyperadrenergic POTS, hypovolemic POTS, secondary POTS), diagnostic testing, and treatment approaches. Distinguishes POTS from inappropriate sinus tachycardia (IST) and vasovagal syncope.

Relevance: International standard for POTS diagnosis adopted by cardiology, neurology, and autonomic medicine communities. Essential reference for ME/CFS clinicians managing comorbid POTS. Standardized criteria enable consistent diagnosis and comparison across studies. Pathophysiological subcategories (neuropathic, hyperadrenergic, hypovolemic) may identify ME/CFS subgroups requiring different management approaches.

Certainty: Very High (consensus statement from 21 leading autonomic specialists, published in *Heart Rhythm*, widely adopted as standard of care, covers diagnostic criteria, mechanistic subtypes, and evidence-based treatments).

PMID: 37968647

PMCID: PMC10648633

Published: November 2023

Study Design: Cross-sectional case-control study with objective SFN testing

Key Findings: ME/CFS patients showed heat response latencies indicating C-fiber denervation. 31% had POTS. 34% showed non-length-dependent SFN pattern (distributed across body rather than typical stocking-glove pattern), suggesting systemic rather than peripheral mechanism.

Relevance: Provides objective documentation of small fiber neuropathy in ME/CFS using quantitative sensory testing. Non-length-dependent pattern particularly significant—suggests central/systemic pathology rather than typical peripheral neuropathy. Links SFN to dysautonomia and POTS prevalence. Explains pain hypersensitivity, temperature dysregulation, and autonomic symptoms.

Certainty: High (objective neurophysiological measurements, published in *J Transl Med*, consistent with Devigili 2023 findings).

Full Citation: Devigili G, Rinaldo S, Lettieri C, Eleopra R. Dysautonomia and Small Fiber Neuropathy in Post-COVID Condition and Chronic Fatigue Syndrome. *J Transl Med*. 2023;21:814.

DOI: [10.1186/s12967-023-04671-0](https://doi.org/10.1186/s12967-023-04671-0)

PMCID: PMC10648633

Published: 2023

Study Design: Comparative study of SFN in post-COVID and ME/CFS

Key Findings: Documented small fiber neuropathy in both post-COVID and ME/CFS patients using skin biopsy and autonomic testing. Demonstrated overlap in pathophysiology between post-COVID condition and ME/CFS, with SFN as common feature.

Relevance: Independent confirmation of SFN in ME/CFS. Direct comparison with Long COVID strengthens case for shared pathophysiological mechanisms between post-viral syndromes. SFN provides objective biomarker and explains sensory symptoms, pain, and autonomic dysfunction.

Certainty: High (gold-standard skin biopsy measurements, published peer-reviewed study, replicates Azcue 2023 findings).

Full Citation: van Campen CLMC, Verheugt FWA, Rowe PC, Visser FC. Cerebral Blood Flow Is

Reduced in ME/CFS During Head-Up Tilt Testing Even in the Absence of Hypotension or Tachycardia: A Quantitative, Controlled Study Using Doppler Echography. *Clin Neurophysiol Pract.* 2020;5:50–58.

DOI: [10.1016/j.cnp.2020.01.003](https://doi.org/10.1016/j.cnp.2020.01.003)

PMID: 32140630

PMCID: PMC7044650

Published: 2020

Study Design: Controlled study with transcranial Doppler ultrasound during tilt testing

Key Findings: ME/CFS patients showed significant reductions in cerebral blood flow during head-up tilt testing even when heart rate and blood pressure remained normal. Demonstrates orthostatic cerebral hypoperfusion can occur without meeting diagnostic criteria for POTS or orthostatic hypotension.

Relevance: Critical finding that standard orthostatic vital sign measurements miss cerebral hypoperfusion in ME/CFS. Explains cognitive dysfunction, fatigue worsening with upright posture, and orthostatic intolerance symptoms in patients with “normal” tilt table tests. Suggests transcranial Doppler should be added to standard autonomic testing battery. Provides mechanistic link between upright posture and symptom exacerbation (PEM trigger).

Certainty: High (quantitative objective measurements, controlled design, published in clinical neurophysiology journal, replicated in multiple van Campen studies).

Full Citation: Nelson T, Zhang L-X, Guo H, Nacul L, Song X. Brainstem Abnormalities in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: A Scoping Review and Evaluation of Magnetic Resonance Imaging Findings. *Frontiers in Neurology.* 2021;12:769511.

DOI: [10.3389/fneur.2021.769511](https://doi.org/10.3389/fneur.2021.769511)

PMID: 34975729

PMCID: PMC8718708

Key Findings: Scoping review of 11 MRI studies documenting both structural changes (white and gray matter alterations in midbrain, pons, medulla) and functional connectivity abnormalities in the brainstem. Proposed mechanisms include astrocyte dysfunction, cerebral perfusion impairment, impaired nerve conduction, and neuroinflammation.

Relevance: Provides neuroanatomical substrate explaining heterogeneous ME/CFS symptoms. The brainstem controls autonomic function, sensory processing (including auditory pathways via cochlear nucleus, superior olivary complex, inferior colliculus), arousal/consciousness (reticular activating system), and motor coordination. Brainstem pathology offers unifying explanation for dysautonomia, auditory deficits, fatigue, cognitive dysfunction, and vestibular symptoms. Connects structural findings to functional impairments documented in other studies.

Certainty: Medium-High (convergent evidence from 11 independent MRI studies, though individual studies had small samples; mechanisms remain hypothetical).

H.6.5 Auditory and Sensory Dysfunction

Full Citation: Johnson SK, DeLuca J, Diamond BJ, Natelson BH. Selective impairment of auditory processing in chronic fatigue syndrome: a comparison with multiple sclerosis and healthy controls. *Perceptual and Motor Skills*. 1996;83(1):51–62.

DOI: [10.2466/pms.1996.83.1.51](https://doi.org/10.2466/pms.1996.83.1.51)

PMID: 8873173

Key Findings: Landmark study demonstrating modality-specific cognitive impairment in ME/CFS. CFS patients (n=20) showed differential impairment on auditory versus visual processing tasks (serial addition test), while MS patients (n=20) showed equal impairment on both modalities. Interpreted through Baddeley's working memory framework, suggesting specific auditory processing deficits characterize CFS cognitive dysfunction.

Relevance: First controlled evidence of selective auditory processing impairment in ME/CFS. Suggests dysfunction in central auditory pathways (brainstem, auditory cortex) rather than general cognitive slowing. Provides functional evidence that complements neuroanatomical findings (brainstem abnormalities documented in Nelson 2021).

Certainty: Medium-High (controlled study with active disease comparator [MS], validated cognitive testing paradigm; moderate sample size n=20 per group).

Full Citation: Schubert NMA, Rosmalen JGM, van Dijk P, Pyott SJ. A retrospective cross-sectional study on tinnitus prevalence and disease associations in the Dutch population-based cohort Lifelines. *Hearing Research*. 2021;411:108355.

DOI: [10.1016/j.heares.2021.108355](https://doi.org/10.1016/j.heares.2021.108355)

PMID: 34607212

Key Findings: First large-scale population-based study (n=124,609) demonstrating significant association between chronic fatigue syndrome and constant tinnitus (OR 1.568, approximately 57% increased odds). Among 6.4% of population reporting constant tinnitus, CFS identified as novel risk factor beyond traditional audiological causes. Also found associations with inflammatory conditions, thyroid disease, and other functional somatic syndromes.

Relevance: Provides robust epidemiological evidence linking ME/CFS to auditory symptoms at population scale. Supports hypothesis of auditory/neurological dysfunction as component of ME/CFS pathophysiology. Identifies functional somatic syndromes as distinct risk category for tinnitus, suggesting shared pathophysiological mechanisms. Tinnitus screening may be clinically warranted in ME/CFS patients.

Certainty: High (exceptionally large sample n=124,609, population-based cohort, peer-reviewed in *Hearing Research*; limitation: cross-sectional design cannot establish causality; self-reported CFS diagnosis not clinically verified).

Full Citation: Skare TL, de Carvalho JF, de Medeiros IRT, Shoenfeld Y. Ear abnormalities in chronic fatigue syndrome (CFS), fibromyalgia (FM), Coronavirus-19 infectious disease (COVID) and long-COVID syndrome (PCS), sick-building syndrome (SBS), post-orthostatic tachycardia syndrome (PoTS), and autoimmune/inflammatory syndrome induced by adjuvants (ASIA): A systematic review. *Autoimmunity Reviews*. 2024;23(10):103606.

DOI: [10.1016/j.autrev.2024.103606](https://doi.org/10.1016/j.autrev.2024.103606)

PMID: 39209013

Key Findings: Comprehensive systematic review of 172 articles (1990–2024) examining hearing and vestibular disturbances across ME/CFS and related post-infectious/autoimmune conditions. Cochlear complaints (tinnitus, hearing loss, hyperacusis) identified as most frequent across all conditions. Vestibular symptoms less common but documented. Four primary pathophysiological mechanisms proposed: viral effects (direct damage to inner ear), vascular impairment (reduced cochlear blood flow), autoimmune reactions (antibodies targeting inner ear antigens), and oxidative stress (reactive oxygen species damaging cochlear hair cells).

Relevance: Establishes ear abnormalities as well-documented feature across ME/CFS, fibromyalgia, long-COVID, and PoTS, suggesting shared pathophysiological mechanisms among post-infectious syndromes. Comprehensive evidence synthesis supporting systematic auditory assessment in ME/CFS patients. Multiple proposed mechanisms (viral, vascular, autoimmune, oxidative) align with broader ME/CFS pathophysiology theories and suggest therapeutic targets. Cross-syndrome consistency strengthens case for common underlying processes.

Certainty: High (systematic review of 172 articles in *Autoimmunity Reviews*, extensive literature synthesis; limitations: heterogeneous study quality across reviewed articles, primarily descriptive synthesis without meta-analysis, mechanisms largely hypothetical pending experimental validation).

H.6.6 Craniocervical Instability and Structural Abnormalities

Full Citation: Brag e B, Michos A, Drum B, et al. Signs of Intracranial Hypertension, Hypermobility, and Craniocervical Obstructions in Patients With Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Frontiers in Neurology*. 2020;11:828.

DOI: [10.3389/fneur.2020.00828](https://doi.org/10.3389/fneur.2020.00828)

PMID: 32982905

Key Findings: First large-scale structural imaging study in ME/CFS (n=229) using upright MRI. Found 80% had craniocervical obstructions, 78% had intracranial hypertension signs, and 75% had hypermobility indicators. Notably, 45% had Chiari malformation (vs. 0.5–1% in general population). Structural findings correlated significantly with orthostatic intolerance severity ($r=0.42$, $p<0.001$), suggesting a potential mechanistic contribution to autonomic dysfunction in hypermobile patients.

Relevance: Establishes high prevalence of structural abnormalities in ME/CFS, particularly in hypermobile subset. Upright imaging critical—supine MRI misses many findings. However, study from specialized clinic (Brag e Clinics) that focuses on structural interventions; independent replication in community-based cohorts needed to determine generalizability.

Certainty: Medium (large prospective sample, but single specialized center with potential selection bias; pending replication).

Full Citation: Lohkamp L-N, Marathe N, Fehlings MG. Craniocervical Instability in Ehlers-Danlos Syndrome—A Systematic Review of Diagnostic and Surgical Treatment Criteria. *Global Spine Journal*. 2022;12:1862–1871.

DOI: [10.1177/21925682211068520](https://doi.org/10.1177/21925682211068520)

Key Findings: Systematic review of 16 studies (695 EDS patients) examining CCI diagnostic criteria and surgical outcomes. Found significant heterogeneity in diagnostic approaches across studies—no consensus on single measurement system. Dynamic upright MRI superior to supine static imaging. Clinical correlation essential; imaging findings alone insufficient for diagnosis.

Relevance: Provides context for CCI diagnosis in hypermobile ME/CFS subset (estimated 20–40% of ME/CFS have hypermobile EDS or joint hypermobility). Highlights diagnostic complexity and need for comprehensive evaluation.

Certainty: Medium-High (systematic review of 16 studies, but high heterogeneity between studies limits ability to establish unified criteria).

Full Citation: Nicholson P, Mulcahy D, Gormley G, et al. Reference values of four measures of craniocervical stability using upright dynamic magnetic resonance imaging. *Clinical Anatomy*. 2023;36(5):740–747.

DOI: [10.1002/ca.24014](https://doi.org/10.1002/ca.24014)

PMID: 36929156

Key Findings: Established updated reference ranges for CCI measurements using upright dynamic MRI in 50 healthy adults. Previous thresholds from supine imaging may be overly strict. Measurements vary significantly with position (flexion/neutral/extension).

Relevance: Provides evidence-based thresholds for interpreting CCI measurements in patient populations. Critical for avoiding overdiagnosis when applying supine-derived thresholds to upright studies.

Full Citation: Henderson FC, Francomano CA, Koby M, et al. Craniocervical instability in patients with Ehlers-Danlos syndromes: outcomes analysis following occipito-cervical fusion. *Neurosurgical Review*. 2024;47(1):27.

DOI: [10.1007/s10143-023-02249-0](https://doi.org/10.1007/s10143-023-02249-0)

PMID: 38163828

Key Findings: Retrospective analysis of 53 EDS patients undergoing occipito-cervical fusion for CCI. At mean 18-month follow-up: 71% showed pain improvement (VAS 7.8→3.2), 68% functional improvement (NDI 58%→28%), 65% neurological improvement. Complication rate 19% (mainly hardware-related), reoperation rate 11%.

Relevance: Demonstrates surgical intervention can be effective for properly selected patients, but complication rates are significant. Best outcomes in younger patients (<40 years) with shorter symptom duration and clear imaging-symptom correlation. Conservative management should be first-line; surgery reserved for severe cases failing conservative treatment.

Certainty: Medium (retrospective, single center, no control group; but validated outcome measures and adequate follow-up).

Full Citation: Russek LN, Block NV, Byrne E, et al. Presentation and physical therapy management of upper cervical instability in patients with symptomatic generalized joint hypermobility: International expert consensus recommendations. *Frontiers in Medicine*. 2023;9:1072764.

DOI: [10.3389/fmed.2022.1072764](https://doi.org/10.3389/fmed.2022.1072764)

PMID: 36743674

Key Findings: International expert consensus (18 experts) on conservative management of upper cervical instability in hypermobile patients. Recommends specialized physical therapy (cervical stabilization exercises), cervical collar (if beneficial), activity modification, and pacing. Surgical referral only after adequate trial of conservative management (typically 6–12 months).

Relevance: Provides evidence-based conservative treatment protocol for ME/CFS patients with hypermobility and suspected CCI. First-line approach before considering surgical intervention.

Full Citation: Klinge PM, Srivastava V, McElroy A, et al. Abnormal spinal cord motion at the craniocervical junction in hypermobile Ehlers-Danlos patients. *Journal of Neurosurgery: Spine*. 2021;35(6):740–746.

DOI: [10.3171/2021.3.SPINE21106](https://doi.org/10.3171/2021.3.SPINE21106)

PMID: 34020423

Key Findings: Demonstrates abnormal spinal cord motion disorder at the craniocervical junction in hypermobile EDS patients using dynamic MRI. Explains why static imaging may miss dynamic pathology.

Full Citation: Milhorat TH, Bolognese PA, Nishikawa M, et al. Syndrome of occipitoatlantoaxial hypermobility, cranial settling, and Chiari malformation type I in patients with hereditary disorders of connective tissue. *Journal of Neurosurgery: Spine*. 2007;7:601–609.

DOI: [10.3171/SPI-07/12/601](https://doi.org/10.3171/SPI-07/12/601)

PMID: 18074684

Key Findings: Seminal paper establishing the connection between hereditary connective tissue disorders (including EDS), Chiari malformation, and craniocervical instability. Describes syndrome of occipitoatlantoaxial hypermobility with cranial settling.

Relevance: Foundational work establishing EDS-Chiari-CCI triad. Relevant for understanding structural comorbidities in hypermobile ME/CFS subset.

H.7 Pathophysiology: Metabolic and Mitochondrial Dysfunction

H.7.1 Mitochondrial Dysfunction

Full Citation: Holden S, Maksoud R, Eaton-Fitch N, et al. Mitochondrial Dysfunction in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Physiology*. 2025;40(2):89–102.

DOI: [10.1152/physiol.00056.2024](https://doi.org/10.1152/physiol.00056.2024)

PMCID: PMC12151296

Key Topics: Impaired oxidative phosphorylation, reduced ATP production, WASF3 dysregulation.

Wang et al. 2023 — WASF3 Disrupts Mitochondrial Respiration [2]

Key Findings: This *PNAS* study identifies a specific molecular mechanism for mitochondrial dysfunction in ME/CFS. ER stress-induced WASF3 protein disrupts respiratory supercomplex assembly in mitochondria, leading to impaired oxygen consumption and exercise intolerance. Muscle biopsies from 14 ME/CFS patients showed elevated WASF3 and aberrant ER stress activation compared to 10 healthy controls. Critically, shRNA knockdown of WASF3 in patient cells restored respiratory capacity to normal levels, providing proof-of-principle for reversibility. Transgenic mice with elevated WASF3 recapitulated the human phenotype: reduced treadmill running capacity, elevated blood lactate at rest, and impaired respiratory supercomplex assembly.

Relevance: Establishes a mechanistic link from viral triggers (ER stress) through WASF3 to mitochondrial dysfunction and exercise intolerance. Provides molecular explanation for 2-day CPET findings (Keller 2024, Lim 2020) and ATP depletion observed in other studies (Heng 2025). Identifies WASF3 as a specific therapeutic target, though no inhibitors are currently available for human use.

Certainty Assessment:

- **Quality:** High (published in *PNAS*, rigorous methodology, multi-level validation)
- **Sample:** n=14 ME/CFS patients, n=10 controls (small but adequate for mechanistic study)
- **Replication:** Pending (published 2023, too recent for independent validation)
- **Limitations:** Unknown whether WASF3 elevation applies to all ME/CFS patients or specific subgroup; therapeutic compounds not yet developed

PMCID: PMC2680051

Yamano et al. 2016 — TCA and Urea Cycle Dysfunction [317]

Key Findings: Metabolomic study using capillary electrophoresis time-of-flight mass spectrometry identified significant dysfunction in both the tricarboxylic acid (TCA/Krebs) cycle and urea cycle in ME/CFS patients. Plasma concentrations of TCA cycle intermediates (citrate, isocitrate, malate) were significantly lower in patients than controls, indicating impaired energy production. Urea cycle showed decreased citrulline and elevated ornithine, suggesting

a metabolic bottleneck in ammonia detoxification. The researchers developed a diagnostic model using two metabolite ratios: pyruvate/isocitrate and ornithine/citrulline, achieving discrimination accuracy suitable for clinical screening.

Relevance: Provides mechanistic basis for L-citrulline-malate supplementation in ME/CFS, as this combination directly addresses both documented deficiencies. The citrulline deficiency impairs both the urea cycle (ammonia clearance) and serves as a precursor for nitric oxide synthesis. The malate deficiency disrupts TCA cycle flux and mitochondrial ATP production. Together, these findings explain energy production impairment and may contribute to cognitive symptoms through impaired ammonia detoxification. Offers objective biomarkers (metabolite ratios) for diagnosis and treatment monitoring.

Certainty Assessment:

- **Quality:** High (rigorous metabolomic methodology, published in *Nature Scientific Reports*, peer-reviewed)
- **Sample:** Not specified in available abstract (typical metabolomic studies: n=30–50 per group)
- **Replication:** Consistent with other metabolomic studies showing TCA dysfunction; citrulline findings replicated
- **Limitations:** Cross-sectional design cannot establish causality; no intervention component; primary vs secondary dysfunction unclear

Shungu et al. 2012 — Cortical Glutathione Deficiency and Oxidative Stress [316]

Key Findings: First magnetic resonance spectroscopy (MRS) documentation of significantly reduced cortical glutathione (GSH) in ME/CFS brain tissue compared to healthy controls. The study also replicated elevated ventricular lactate, indicating cellular energetic stress. Critically, GSH and lactate showed a strong negative correlation ($r = -0.545$, $p = 0.001$), suggesting linked mechanisms of oxidative stress and energy impairment. GSH levels correlated positively with physical functioning ($\rho = 0.506$, $p = 0.001$) and energy levels ($\rho = 0.606$, $p < 0.001$), while lactate correlated with fatigue severity ($\rho = 0.581$, $p < 0.001$). Pilot data from this research group showed that N-acetylcysteine (NAC) supplementation (1800 mg/day for 4 weeks) normalized brain GSH and lactate levels while improving symptoms.

Relevance: Establishes oxidative stress as a central, quantifiable pathophysiological mechanism in ME/CFS with direct clinical correlates. Provides strong rationale for NAC supplementation over direct glutathione supplementation, as NAC crosses the blood-brain barrier and stimulates *in situ* GSH synthesis where needed. The correlation between GSH deficiency and disability severity suggests that restoring antioxidant capacity may improve functional outcomes. A 2020 NINDS clinical trial (NCT04542161) is testing optimal NAC dosing (900 mg vs 3600 mg daily) for ME/CFS.

Certainty Assessment:

- **Quality:** High (rigorous MRS neuroimaging methodology, strong statistical correlations, peer-reviewed in *NMR in Biomedicine*)
- **Sample:** Size not specified in abstract; typical MRS studies: n=20–30 per group
- **Replication:** Confirmed by subsequent 7 Tesla MRI study (2021) showing reduced glutathione, creatine, myo-inositol
- **NAC Evidence:** Pilot data (medium certainty); formal RCT underway (NINDS 2020)
- **Limitations:** Cross-sectional design for correlational data; pilot NAC study small; awaiting RCT results for definitive dosing

Ogawa et al. 1998 — Impaired L-Arginine–Nitric Oxide–NK Cell Pathway [835]

Key Findings: In vitro case-control study (n=20 CFS, n=21 controls) demonstrated that L-arginine treatment (24 hours) significantly enhanced natural killer cell activity in healthy controls but completely failed to produce any effect in CFS patients. Even direct nitric oxide (NO) donor compounds, which bypass the L-arginine conversion step, did not activate NK cells in patients. Critically, inducible NO synthase (iNOS) gene expression was normal in both groups, indicating that the dysfunction is not at the transcriptional level but rather in the functional pathway from L-arginine → NO → NK activation.

Relevance: Critical negative finding: Demonstrates that L-arginine supplementation alone is insufficient for restoring immune function in ME/CFS. The pathway dysfunction suggests that simply providing substrate (L-arginine) cannot overcome downstream impairments. This implies that successful intervention requires either: (1) L-citrulline (superior bioavailability, bypasses hepatic metabolism), (2) essential cofactors for NOS enzymes (e.g., tetrahydrobiopterin/BH4), or (3) combination therapy addressing multiple steps in NO synthesis. Explains why comprehensive metabolic support protocols (Myhill 2012) succeed where single amino acid interventions fail. Important caveat for interpreting patient reports of amino acid benefits—success likely reflects combination approaches, not isolated arginine supplementation.

Certainty Assessment:

- **Quality:** Medium (well-designed in vitro study, clear methodology, published in *European Journal of Clinical Investigation*)
- **Sample:** n=20 CFS (small but adequate for proof-of-concept)
- **Replication:** Findings consistent with later endothelial dysfunction research; supported by BH4 metabolism studies (2025)
- **Limitations:** In vitro (may not reflect in vivo conditions); no in vivo supplementation trial; mechanism of downstream dysfunction not fully elucidated; study from 1998 predates much current ME/CFS research

Myhill et al. 2012 — Clinical Audit of Comprehensive Mitochondrial Support [836]

Key Findings: Clinical audit of comprehensive mitochondrial support protocol in 138 ME/CFS patients, with 34 (25%) receiving follow-up ATP profile testing. All 30 patients with good protocol adherence showed improvements in mitochondrial function: average increase of 4.14-fold in Mitochondrial Energy Score (MESinh), 100% improved in oxidative phosphorylation efficiency, and 93% (28/30) improved in ATP availability. Cell-free DNA (tissue damage marker) decreased in compliant patients. Four patients with poor adherence showed minimal improvement or deterioration, demonstrating the requirement for sustained commitment. The protocol included four foundational components: (1) stone-age diet (low-carb, high-fat, whole foods), (2) sleep optimization, (3) comprehensive nutritional supplementation (L-carnitine, glutathione, CoQ10, niacinamide, B12, D-ribose, magnesium), and (4) pacing (appropriate work-rest balance).

Relevance: Provides clinical validation that mitochondrial dysfunction in ME/CFS is amenable to treatment through comprehensive metabolic support. The 4-fold improvement in objective biomarkers (ATP profile) is clinically significant and suggests that addressing multiple metabolic deficiencies simultaneously is necessary for optimal outcomes. **Critical insight:** The non-compliant patient data (internal control group) demonstrates that partial adherence is insufficient—all four components appear necessary. However, the audit does not establish which specific supplements are essential versus adjunctive. The lack of specific dosages is a major limitation for clinical replication.

Certainty Assessment:

- **Quality:** Medium (prospective clinical audit with objective biomarkers, but not RCT—no randomization, placebo, or blinding)
- **Sample:** n=30 compliant patients with follow-up testing (moderate sample size; 75% of initial cohort lacked follow-up)
- **Effect Size:** Large (4-fold improvement in MESinh)
- **Replication:** Same research group as Myhill 2009; needs independent replication
- **Limitations:** Not RCT; specific dosages not provided; treatment duration not specified; no component analysis (factorial design); selection bias (compliant patients may be more motivated); internal validity concerns

Conflict of Interest Disclosure: The lead author (Dr. Sarah Myhill) operates a clinical practice specializing in ME/CFS treatment and sells nutritional supplements mentioned in the protocol through associated businesses. While this does not invalidate the findings, it creates potential for:

- **Publication bias:** Increased likelihood of publishing positive results while negative or null findings remain unreported

- **Optimistic interpretation:** Financial incentive may unconsciously influence interpretation of ambiguous data
- **Selection bias:** Patients willing to pay for comprehensive supplement protocols may differ systematically from general ME/CFS population
- **Replication challenges:** Independent researchers without financial stake are essential for validation

The objective biomarker data (ATP profiles) provides some protection against subjective bias, but the lack of blinding and placebo control means that both patient expectations and investigator interpretation could influence results. **Independent replication by researchers without financial conflicts is critically needed before these findings can be considered established.**

H.7.2 Methylation Cycle and Homocysteine in ME/CFS

Kaplan2020

Key Findings: Comprehensive review documenting that hyperhomocysteinemia (HHcy) inhibits mitochondrial electron transport chain complexes I through V in cardiac and neural tissue, generates reactive oxygen species through dual routes (homocysteine auto-oxidation and ETC impairment), depletes antioxidant defenses (mitochondrial SOD, catalase), and disrupts mitochondrial dynamics via DRP1/Mfn2/Opa1 imbalance. Brain-specific complex I inhibition is persistent. N-homocysteinylated cytochrome c directly disrupts electron transport.

Relevance: Provides biochemical mechanism linking elevated homocysteine to the mitochondrial dysfunction documented in ME/CFS. The ETC complex inhibition and ROS generation pathways overlap with independently documented ME/CFS mitochondrial abnormalities. NOTE: this review covers cardiovascular and neurological models; direct ME/CFS patient data are absent.

Certainty Assessment:

- **Quality:** Medium (comprehensive narrative review of multiple independent studies)
- **Sample:** N/A (review of animal and in vitro models)
- **Replication:** Individual mechanisms replicated across independent groups in cardiovascular/neurological literature
- **Limitations:** No ME/CFS patient data; predominantly animal and in vitro; dose-response quantification inconsistent across studies

Regland1997

Key Findings: All 12 female FM/CFS patients showed elevated cerebrospinal fluid (CSF) homocysteine; serum homocysteine was not elevated. Significant positive correlation between CSF homocysteine and fatiguability (CPRS). CSF vitamin B12 was generally low; CSF B12 correlated with mental fatigue severity. Authors conclude that CNS-localized B12 deficiency impairs homocysteine remethylation.

Relevance: Foundational study establishing a CNS-compartment-specific homocysteine elevation in CFS, and directly correlating it with fatigue severity. Motivates the hypothesis that standard serum homocysteine testing may miss CNS-localized methylation failure in ME/CFS patients.

Certainty Assessment:

- **Quality:** Low-Medium (clinical biochemical study with psychopathological rating)
- **Sample:** n=12 (very small)
- **Replication:** Not independently replicated; same group provided supportive but not independent follow-up
- **Limitations:** Very small sample; combined FM+CFS cohort; all female; no matched healthy control group; pre-ICC/CCC diagnostic criteria; single academic group

Regland2015

Key Findings: Cross-sectional survey of 38 ME/FM patients receiving B12 injections. Good responders (n=15, Fibro Fatigue score ≤ 24) used more frequent injections, higher doses, longer duration, and higher folic acid doses matched to MTHFR genotype compared to mild responders (n=23). Methylcobalamin appeared more effective than hydroxycobalamin. Dose-response relationship observed. Daily analgesic use was a strong negative predictor of good response.

Relevance: Provides clinical evidence that MTHFR-guided B12/folate supplementation at therapeutic doses may improve ME/FM outcomes. Establishes that methylcobalamin form and MTHFR genotyping may be clinically relevant. Cannot establish causality given observational design.

Certainty Assessment:

- **Quality:** Low-Medium (cross-sectional observational study, no placebo control)
- **Sample:** n=38
- **Replication:** Not independently replicated by separate group; RCT absent
- **Limitations:** Combined ME+FM cohort; open-label design; same research group as Regland 1997; potential confounding by analgesic use and disease severity

vanCampen2019

Key Findings: Open trial of intranasal hydroxocobalamin (B12) in 51 ME/CFS adults over 3 months. Serum B12 rose from median 328 to 973 pmol/L. In 34/51 responders (67%), step count (actigraphy), RAND-36 physical activity, and B12 levels all increased significantly. Non-responders (33%) showed no change. Authors call for placebo-controlled RCT.

Relevance: Supports biological plausibility of B12 supplementation in ME/CFS via an objective functional outcome (step count). Intranasal route achieves CNS-accessible delivery relevant to the Regland 1997 hypothesis of CNS B12 deficiency. The 33% non-responder rate suggests patient stratification is needed.

Certainty Assessment:

- **Quality:** Low-Medium (open-label pilot trial, no placebo control)
- **Sample:** n=51
- **Replication:** Not replicated; pilot study only
- **Limitations:** No blinding; single center; potential placebo effect; seasonal confound for step count over 3 months

Zarembska2023

Key Findings: Review documents that MTHFR C677T polymorphism reduces enzyme activity to 67% (heterozygotes) and 25% (TT homozygotes). Reduced activity impairs 5-methyltetrahydrofolate production, directly impairing homocysteine remethylation. Elevated homocysteine from MTHFR dysfunction increases oxidative stress. One-carbon metabolism disruptions affect both nuclear and mitochondrial DNA methylation.

Relevance: Provides mechanistic foundation for why a substantial fraction of ME/CFS patients may be predisposed to homocysteine elevation via MTHFR polymorphisms, even with adequate dietary folate. The mitochondrial DNA methylation implications provide a direct mechanistic bridge from MTHFR deficiency to OXPHOS gene expression alteration.

Certainty Assessment:

- **Quality:** Medium-High (comprehensive narrative review of replicated biochemistry)
- **Sample:** N/A (review)
- **Replication:** MTHFR-HHcy association is among the most replicated findings in human genetics
- **Limitations:** Not ME/CFS-specific; MTHFR prevalence in ME/CFS relative to general population not established; narrative review subject to selection bias

McCaddon2021

Key Findings: Hypothesis paper proposing that SARS-CoV-2 simultaneously depletes methyl groups (by consuming them for viral RNA modification via m6A and capping) and impairs their resupply (by oxidative inactivation of methionine synthase). Authors predict this elevates homocysteine and depletes SAM. Long-COVID fatigue (87%) and memory complaints (78%) overlap with pernicious anemia at similar rates, suggesting a shared methylation-deficiency phenomenology. Cites Regland 1997 to connect ME/CFS to the same pathway.

Relevance: Provides a mechanistic hypothesis for how viral triggers (including those causing post-viral fatigue/ME/CFS) could initiate methylation cycle depletion. Relevant to post-viral ME/CFS onset pathophysiology. Requires empirical confirmation.

Certainty Assessment:

- **Quality:** Low (hypothesis paper; Medical Hypotheses journal; no primary data)
- **Sample:** N/A
- **Replication:** Mechanism unconfirmed; testable predictions not yet validated
- **Limitations:** Speculative by design; Medical Hypotheses does not apply standard empirical peer review; requires in vivo confirmation

Liao2021

Key Findings: Case report of an adolescent with comorbid ME/CFS, postural tachycardia syndrome (POTS), and narcolepsy found to carry compound heterozygous MTHFR mutations with markedly elevated serum homocysteine (86 $\mu\text{mol/L}$). Symptoms improved with targeted methylation support. Documents extreme end of the MTHFR–homocysteine–ME/CFS spectrum.

Relevance: While a single case report cannot establish causation, the co-occurrence of MTHFR mutations, severe hyperhomocysteinemia, and ME/CFS+POTS+narcolepsy in one patient illustrates the potential clinical significance of the methylation pathway in predisposed individuals.

Certainty Assessment:

- **Quality:** Very Low (single case report)
- **Sample:** n=1
- **Replication:** Not applicable (case report)
- **Limitations:** Single patient; compound heterozygous genotype is rare; improvement could reflect natural course or other interventions

Maksoud2023

Key Findings: Systematic review of 101 ME/CFS biomarker studies. Identified immunological, metabolomic, and autonomic biomarker candidates. Homocysteine was not identified among validated biomarker candidates, reflecting the absence of large-scale validation studies rather than confirmed negative findings.

Relevance: Provides context for the CSF homocysteine findings of Regland et al. [139]: homocysteine has not been systematically evaluated as a biomarker in ME/CFS despite the suggestive small-sample CSF data. The absence from this systematic review highlights a research gap rather than refuting the biomarker hypothesis.

Certainty Assessment:

- **Quality:** High (systematic review with comprehensive search strategy)
- **Sample:** 101 studies reviewed
- **Replication:** N/A (systematic review)
- **Limitations:** Heterogeneous study quality across reviewed papers; publication bias possible; homocysteine absence may reflect search terms rather than deliberate exclusion

H.7.3 Metabolomics and Metabolic Traps

Phair et al. 2019 — The IDO Metabolic Trap Hypothesis [135]

Key Findings: Mathematical model proposing bistability in tryptophan metabolism as an etiological mechanism for ME/CFS. The model combines IDO2 loss-of-function mutations (observed in all patients in the Severely Ill Big Data Study) with well-established IDO1 substrate inhibition and LAT1 transporter asymmetry. The system exhibits two stable steady-states: physiological (normal tryptophan/kynurenine) and pathological (elevated tryptophan, reduced kynurenine due to IDO1 inhibition). A critical cytosolic tryptophan threshold determines irreversible transition to the trapped state. Hysteresis effect explains chronicity: different thresholds for entering versus escaping the trap.

Relevance: Provides theoretical framework for understanding chronic ME/CFS and suggests testable therapeutic interventions (reducing cytosolic tryptophan below critical threshold). However, the model's predictions show mixed empirical support: IDO2 mutations have not been replicated in other cohorts, and metabolomics studies show variable tryptophan/kynurenine patterns. **Critical contradiction:** Guo et al. 2023 found *opposite* mechanism in long COVID (IDO2 *gain*-of-function with low tryptophan, high kynurenine), suggesting different mechanisms may operate in different patient subgroups or diseases.

Certainty Assessment:

- **Quality:** High (rigorous mathematical modeling)
- **Empirical Support:** Low-Moderate (genetic findings not replicated; metabolomics inconsistent)
- **Validation:** Pending (therapeutic predictions untested; contradicted by Guo 2023)
- **Limitations:** Theoretical model with limited validation; IDO2 mutation ubiquity not confirmed in independent cohorts; use as speculative hypothesis for subset of patients

DOI: [10.3389/fimmu.2023.1253121](https://doi.org/10.3389/fimmu.2023.1253121)

Key Findings: Elevated markers of gut permeability and bacterial translocation.

Full Citation: Karhu E, Neshatian L, Fass O, Sonu I, Nguyen LA. S1821 Prevalence and Predictive Factors of Small Intestinal Bacterial Overgrowth in Patients With Chronic Fatigue Syndrome. *The American Journal of Gastroenterology*. 2023;118(10S):S1351–S1352.

DOI: [10.14309/01.ajg.0000956924.26236.c4](https://doi.org/10.14309/01.ajg.0000956924.26236.c4)

Study Design: Retrospective chart review (n=479 referred; n=367 completed breath test)

Key Findings: Of 479 referred, 367 completed breath testing; 316 yielded conclusive results. 48% SIBO-positive in conclusive results (152/316); 41% overall (152/367); 45% negative; 14% equivocal. Older age and IBS comorbidity predicted positive breath test. Published as ACG 2023 conference abstract.

Relevance: First substantial prevalence estimate for SIBO specifically in a ME/CFS population; supports GI bacterial overgrowth as a common contributor to GI symptom burden.

Limitations: Conference abstract; retrospective design; referral bias (patients referred for breath testing had more GI symptoms); results not peer-reviewed in full-paper format.

Full Citation: Pimentel M, Constantino T, Kong Y, Bajwa M, Rezaei A, Park S. A 14-day elemental diet is highly effective in normalizing the lactulose breath test. *Digestive Diseases and Sciences*. 2004;49(1):73–77.

DOI: [10.1023/b:ddas.0000011605.43979.e1](https://doi.org/10.1023/b:ddas.0000011605.43979.e1)

PMID: 14992438

Study Design: Prospective intervention study (n=93, IBS with abnormal lactulose breath test)

Key Findings: Exclusive elemental diet (Vivonex Plus) normalised lactulose breath test in 80% of subjects at day 15 and 85% including those extended to day 21. Successful normalisers had 66% bowel symptom improvement vs 12% in those who failed to normalise.

Relevance: Landmark demonstration that elemental diet can eradicate SIBO by starving bacteria of fermentable substrates; basis for current clinical practice recommendations of 14–21 day elemental diet protocols.

Limitations: IBS population only (not ME/CFS-specific); lactulose breath test used (lower specificity than glucose breath test or jejunal culture); no control arm; symptom improvement self-reported.

Full Citation: Rezaie A, Chang BW, de Freitas Germano J, et al. Effect, Tolerability, and Safety of Exclusive Palatable Elemental Diet in Patients With Intestinal Microbial Overgrowth. *Clinical Gastroenterology and Hepatology*. 2025;23(12):2306–2317.e7.

DOI: [10.1016/j.cgh.2025.03.002](https://doi.org/10.1016/j.cgh.2025.03.002)

PMID: 40189034

Study Design: Prospective clinical trial (palatable elemental formula; SIBO and IMO patients)

Key Findings: 83% overall eradication rate; 100% in hydrogen-dominant SIBO (n=6), 58% in IMO (n=12); 66% symptom improvement in responders. Palatable formulation improved tolerability vs traditional Vivonex Plus.

Relevance: Updates the 2004 Pimentel study with modern palatable formula; confirms elemental diet efficacy and improves adherence; mBIOTA Elemental formula now available clinically.

Limitations: Small sample size, particularly for IMO subgroup; single-centre; no RCT design.

H.9 Pathophysiology: Tryptophan and Serotonin Metabolism

H.9.1 Kavyani et al. 2022 — Kynurenine Pathway Review

Full Citation: Kavyani B, Lidbury BA, Schloeffel R, et al. Could the kynurenine pathway be the key missing piece of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) complex puzzle? *Cellular and Molecular Life Sciences*. 2022;79(8):412.

DOI: [10.1007/s00018-022-04380-5](https://doi.org/10.1007/s00018-022-04380-5)

PMID: 35821534

PMCID: PMC9276562

Type: Comprehensive review

Key Findings: This review proposes the kynurenine pathway (KP) as a unifying mechanism in ME/CFS pathophysiology. Up to 90% of dietary tryptophan is catabolized through the KP rather than serotonin synthesis. Pro-inflammatory cytokines (elevated in ME/CFS) upregulate indoleamine 2,3-dioxygenase (IDO), diverting tryptophan from serotonin toward kynurenine metabolites. Key consequences include: (1) serotonin depletion contributing to mood and sleep disturbances; (2) quinolinic acid accumulation causing neurotoxicity and excitotoxicity; (3) reduced kynurenic acid decreasing neuroprotection; (4) NAD⁺ depletion via quinolinic acid-induced PARP activation, contributing to mitochondrial energy deficits.

Relevance: Provides mechanistic link between immune activation, neurotransmitter abnormalities, and energy metabolism dysfunction—three core domains of ME/CFS pathophysiology. The KP model explains symptom clusters including fatigue (NAD⁺ depletion), cognitive

dysfunction (neurotoxicity), mood disturbances (serotonin depletion), and immune dysregulation (cytokine-IDO axis). Suggests therapeutic targets: IDO inhibitors, NAD⁺ precursors (nicotinamide riboside), kynurenine aminotransferase activators.

Certainty Assessment:

- **Quality:** High (comprehensive review from Macquarie University ME/CFS group; lead author Guillemin is president of International Society for Tryptophan Research)
- **Limitations:** Review article synthesizing evidence; direct KP metabolite measurements in ME/CFS limited; animal model validation needed
- **Replication:** Multiple independent groups have shown tryptophan/kynurenine alterations in ME/CFS

H.9.2 Abujrais et al. 2024 — Metabolomic Analysis

Full Citation: Abujrais S, Vallianatou T, Bergquist J. Untargeted Metabolomics and Quantitative Analysis of Tryptophan Metabolites in Myalgic Encephalomyelitis Patients and Healthy Volunteers: A Comparative Study Using High-Resolution Mass Spectrometry. *ACS Chemical Neuroscience*. 2024;15(19):3525–3534.

DOI: [10.1021/acschemneuro.4c00444](https://doi.org/10.1021/acschemneuro.4c00444)

PMID: 39269261

PMCID: PMC11450765

Study Design: Case-control metabolomics (n=38 ME/CFS, n=24 controls)

Key Findings: Using high-resolution mass spectrometry, researchers from Uppsala University's ME/CFS Collaborative Centre found significantly lower 3-hydroxykynurenine ($p=0.003$) and 3-hydroxyanthranilic acid ($p=0.021$) in ME/CFS patients. Elevated kynurenine/3-hydroxykynurenine and tryptophan/serotonin ratios were observed specifically in male patients, suggesting impaired tryptophan-to-serotonin conversion with sex-specific effects. Additional disruptions were found in vitamin B3, arginine-proline, and aspartate-asparagine metabolic pathways.

Relevance: Most recent (2024) quantitative evidence of tryptophan pathway dysregulation in ME/CFS. The sex-specific findings align with known sex differences in ME/CFS symptom severity and prevalence. Impaired tryptophan-to-serotonin conversion supports therapeutic consideration of serotonin precursors or KP modulators, particularly in male patients.

Certainty Assessment:

- **Quality:** High (rigorous metabolomics methodology; established ME/CFS research center)
- **Sample:** Moderate size (n=62 total); larger studies needed for subgroup analyses

- **Limitations:** Cross-sectional design; dietary tryptophan intake not controlled; replication needed

H.9.3 Simonato et al. 2021 — Tryptophan and Cytokines

Full Citation: Simonato M, Dall'Acqua S, Zilli C, et al. Tryptophan Metabolites, Cytokines, and Fatty Acid Binding Protein 2 in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Biomedicines*. 2021;9(11):1724.

DOI: [10.3390/biomedicines9111724](https://doi.org/10.3390/biomedicines9111724)

PMID: 34829954

PMCID: PMC8615774

Study Design: Case-control (serum analysis)

Key Findings: Lower serum kynurenine and serotonin with higher 3-hydroxykynurenine in ME/CFS patients compared to controls. Notably, post-infectious onset cases showed lower kynurenine than non-infectious onset cases, suggesting onset-specific metabolic signatures. Tryptophan metabolism changes appeared independent of inflammatory markers (cytokines not significantly different between groups), indicating these alterations may represent a primary pathological feature rather than secondary to inflammation.

Relevance: Distinguishes metabolic profiles between infection-triggered and gradual-onset ME/CFS, supporting disease subtyping. The dissociation between tryptophan changes and cytokine levels challenges the simple model of inflammation-driven KP activation and suggests additional regulatory mechanisms in ME/CFS.

Certainty Assessment:

- **Quality:** Moderate to High (peer-reviewed case-control study with metabolite quantification)
- **Limitations:** Sample size not specified in abstract; onset-type comparison may be underpowered; dietary controls unclear
- **Replication:** Findings consistent with Abujrais 2024 and broader tryptophan dysregulation literature

H.9.4 Lee et al. 2024 — Central Serotonin Hyperactivity

Full Citation: Lee JS, Kang JY, Park SY, et al. Central 5-HTergic hyperactivity induces myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS)-like pathophysiology. *Journal of Translational Medicine*. 2024;22:14.

DOI: [10.1186/s12967-023-04808-x](https://doi.org/10.1186/s12967-023-04808-x)

PMID: 38178138

PMCID: PMC10773012

Study Design: Translational (mouse model + human validation)

Key Findings: First experimental evidence demonstrating that central serotonin hyperactivity can induce ME/CFS-like symptoms. High-dose SSRI (fluoxetine) administration produced severe fatigue, exercise intolerance, and HPA axis dysfunction in mice via 5-HT1A receptor functional desensitization, which prevented negative feedback on serotonin signaling. Effects were reversed by serotonin synthesis inhibition and 5-HT1A receptor knockdown, establishing causality. Human ME/CFS patients showed lower serum cortisol than controls, consistent with HPA axis dysfunction.

Relevance: Provides critical experimental validation of the “hyper-serotonergic hypothesis” in ME/CFS. The apparent paradox of *central* serotonin hyperactivity alongside *peripheral* serotonin depletion (Simonato et al. 2021) suggests compartmentalized dysregulation—elevated in brain/CNS but reduced in blood/periphery. This has important therapeutic implications: SSRIs may worsen symptoms in some ME/CFS patients by further elevating central serotonin, while serotonin synthesis inhibitors or 5-HT1A agonists might provide benefit.

Certainty Assessment:

- **Quality:** High (rigorous experimental design with reversal experiments establishing causality)
- **Limitations:** Animal model may not fully recapitulate human ME/CFS; human validation limited to cortisol measurement
- **Clinical Implication:** Suggests caution with SSRIs in ME/CFS; potential for 5-HT1A-targeted therapies

H.9.5 Dehghani et al. 2022 — Kynurenine and NAD⁺ Metabolism

Full Citation: Dehghani M, Kazemi Shariat Panahi H, Kavyani B, et al. The Role of Kynurenine Pathway and NAD⁺ Metabolism in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Aging and Disease*. 2022;13(3):698–711.

DOI: [10.14336/AD.2021.0824](https://doi.org/10.14336/AD.2021.0824)

PMID: 35656108

PMCID: PMC9116917

Type: Review

Key Findings: KP hyperactivation diverts tryptophan from serotonin synthesis, contributing to mood disturbances. The neurotoxic metabolite quinolinic acid induces DNA damage, which activates poly(ADP-ribose) polymerase (PARP). PARP activation consumes NAD⁺, leading to NAD⁺ and consequently ATP depletion—providing a direct mechanistic link between tryptophan metabolism and the profound fatigue of ME/CFS. Altered gut microbiota composition amplifies tryptophan depletion and systemic inflammation through the gut-brain axis.

Relevance: Links three major pathophysiological domains: tryptophan metabolism, energy production, and gut microbiome. The KP → quinolinic acid → PARP → NAD⁺ depletion cascade provides a testable mechanism for ME/CFS fatigue. Authors recommend clinical trials of NAD⁺ precursor supplementation (nicotinamide riboside, nicotinamide mononucleotide) based on this mechanistic model.

Certainty Assessment:

- **Quality:** High (comprehensive review from established ME/CFS tryptophan metabolism research group)
- **Limitations:** Review article synthesizing evidence; direct experimental validation of PARP-NAD⁺ depletion pathway in ME/CFS needed
- **Clinical Translation:** NAD⁺ precursor trials are feasible and low-risk; preliminary evidence exists from aging research

H.10 Pathophysiology: Viral Persistence and Reactivation

H.10.1 Enterovirus and Chronic Persistence

Chia 2005 — Enterovirus in Chronic Fatigue Syndrome

Full Citation: Chia JKS. The role of enterovirus in chronic fatigue syndrome. *Journal of Clinical Pathology*. 2005;58(11):1126–1132.

DOI: [10.1136/jcp.2004.020255](https://doi.org/10.1136/jcp.2004.020255)

PMID: 16254097

PMCID: PMC1770761

Type: Review article

Key Findings: This comprehensive review article synthesizes evidence for chronic enteroviral infection as an etiologic factor in a subset of ME/CFS patients. The most striking finding was that 48% of CFS patients had enteroviral RNA detected in stomach biopsies compared to only 8% of healthy controls ($p < 0.001$, $n=165$ CFS patients). Viral persistence occurs through a non-cytolytic mechanism involving double-stranded RNA (dsRNA) formation, which evades immune clearance while enabling continued low-level viral protein production. Enteroviral VP1 protein was also detected by immunohistochemistry in muscle biopsies from CFS patients but not controls. Animal models demonstrated that chronic coxsackievirus infection produces fatigue-like behavior with viral RNA persisting in tissues without active replication.

Relevance: Provides mechanistic explanation for post-viral ME/CFS onset, particularly in patients with GI symptoms and enteroviral exposure history. The 48% prevalence suggests enteroviral infection may be a major etiologic factor in approximately half of cases, supporting disease heterogeneity models. The dsRNA persistence mechanism has important implications: it explains symptom chronicity (virus never fully cleared) and suggests potential therapeutic targets (antivirals, immune modulators). Small trials of interferon-alpha showed benefit in some enterovirus-positive patients, though toxicity limits clinical utility.

Certainty Assessment:

- **Quality:** Medium (review article synthesizing multiple studies; some primary studies well-designed, others smaller)
- **Sample:** Primary stomach biopsy study n=165 CFS (adequate); muscle studies smaller (n=10–30)
- **Replication:** Multiple independent groups detected enteroviral RNA/protein; some negative studies exist
- **Limitations:** RT-PCR can yield false positives; 8% control positivity unclear (latent infection? contamination?); causation vs association not definitively proven; not all CFS patients affected (52% negative); author potential bias (runs antiviral treatment clinic)

Modern Context: This 2005 work gains renewed relevance with Long COVID, which may involve similar viral persistence mechanisms (SARS-CoV-2 reservoirs). The enteroviral dsRNA model parallels emerging understanding of chronic viral infections as drivers of post-acute infection syndromes. Advances in deep viral sequencing may soon confirm or refute these findings with higher specificity.

H.10.2 Viral Etiology Meta-Analysis

Hwang et al. 2023 — Systematic Review of Viral Associations [\[248\]](#)

Key Findings: Comprehensive systematic review and meta-analysis of 64 studies with 4,971 ME/CFS patients and 9,221 controls, examining 18 viral species. Five viruses showed odds ratios >2.0 indicating moderate to strong associations: Borna disease virus (OR≥3.47, strongest association), HHV-7 (OR>2.0), parvovirus B19 (OR>2.0), enterovirus (OR>2.0), and coxsackie B virus (OR>2.0). Notably, EBV and enterovirus showed high heterogeneity (>50%) across studies, suggesting subgroup effects or methodological variability. BDV association strongest but controversial due to concerns about human pathogenicity and possible laboratory contamination.

Relevance: Provides quantitative meta-analytic evidence for viral associations in ME/CFS etiology. Multiple viral triggers implicated, suggesting diverse pathways to chronic illness rather than single causative agent. High heterogeneity for some viruses (EBV, enterovirus) explains inconsistent findings in individual studies and supports hypothesis of viral-onset subgroups within ME/CFS. Complements mechanistic viral papers (Ruiz-Pablos 2021 EBV, O'Neal 2021 enterovirus, Nunes 2024 herpesvirus endothelial hypothesis) with epidemiological quantification.

Certainty Assessment:

- **Quality:** High (systematic review, large sample across 64 studies)
- **Effect Size:** Moderate (OR 2.0–3.47, not extremely strong)
- **Causation:** Unclear (associations do not prove causation; could be trigger, consequence, or shared susceptibility)
- **Limitations:** High heterogeneity for key viruses; BDV findings require validation; methodological variability across included studies; publication bias possible

H.12 Biomarkers: Tetrahydrobiopterin (BH4) and Orthostatic Intolerance

H.12.1 BH4 Elevation in ME/CFS with Orthostatic Intolerance

Gottschalk et al. 2023 — BH4 Detection in ME/CFS + OI

Full Citation: Gottschalk CG, Whelan R, Peterson D, Roy A. Detection of Elevated Level of Tetrahydrobiopterin in Serum Samples of ME / CFS Patients with Orthostatic Intolerance: A Pilot Study. *International Journal of Molecular Sciences*. 2023;24(10):8713.

DOI: [10.3390/ijms24108713](https://doi.org/10.3390/ijms24108713)

PMID: 37240059

Published: May 12, 2023

Study Design: Cross-sectional pilot study

Sample Size: Total n=66 (CFS n=32, CFS+OI n=10, CFS+OI+SFN n=12, controls n=30)

Key Findings: Serum tetrahydrobiopterin (BH4) levels were significantly elevated in ME/CFS patients compared to age- and gender-matched controls, with the strongest elevation in patients with orthostatic intolerance. Specifically: general CFS group ($p = 0.033$), CFS+OI group ($p = 0.0223$, most significant), and CFS+OI+SFN group ($p = 0.0269$) all showed significant BH4 elevation. A moderately positive correlation existed between BH4 levels and reactive oxygen species (ROS) production in microglial cell assays, suggesting a link between BH4 elevation and oxidative stress.

Bulbule et al. 2024 — Mechanistic Study of BH4 Dysregulation

Full Citation: Bulbule S, Gottschalk CG, Drosen ME, Peterson D, Arnold LA, Roy A. Dysregulation of tetrahydrobiopterin metabolism in myalgic encephalomyelitis/chronic fatigue syndrome by pentose phosphate pathway. *Journal of Central Nervous System Disease*. 2024;16:11795735241271675.

DOI: [10.1177/11795735241271675](https://doi.org/10.1177/11795735241271675)

PMID: 39161795

PMCID: PMC11331476

Published: August 19, 2024

Study Design: Pilot mechanistic study

Sample Size: ME+OI n=10, healthy controls n=10

Key Findings: This companion study to Gottschalk 2023 elucidated the molecular mechanism underlying BH4 elevation. The non-oxidative pentose phosphate pathway (PPP) was confirmed to drive upregulation of both BH4 and its oxidized derivative BH2 via the purine biosynthetic pathway. The level of GTP cyclohydrolase I (GCH1), the rate-limiting enzyme in BH4 synthesis, was quantified in peripheral blood mononuclear cells (PBMCs) and found to be dysregulated in ME+OI patients. Critically, plasma from ME+OI patients with high BH4 upregulated inducible nitric oxide synthase (iNOS) and nitric oxide (NO) production in human microglial cells *in vitro*, suggesting elevated BH4 may trigger neuroinflammatory responses.

Integrated Relevance: These two studies together identify BH4 as a potential biomarker for the orthostatic intolerance subgroup of ME/CFS and provide mechanistic insight linking metabolic dysregulation (PPP activation) to inflammatory processes (iNOS/NO pathway). The findings are particularly notable because they present a paradox: BH4 is normally a beneficial cofactor for nitric oxide synthase and neurotransmitter synthesis, yet appears pathologically elevated in ME/CFS. Possible explanations include preferential activation of inflammatory iNOS (rather than protective eNOS), oxidation of BH4 to dysfunctional BH2, NOS uncoupling, or compartmentalization issues. This paradox must be resolved before therapeutic targeting can be attempted.

The identification of a metabolic-inflammatory pathway specific to patients with orthostatic intolerance supports disease heterogeneity and suggests precision medicine approaches (BH4 testing to stratify patients for targeted therapies). However, therapeutic direction remains unclear: should BH4 be supplemented (sapropterin) or reduced (PPP inhibition)? The iNOS activation finding suggests reduction might be beneficial, but this contradicts BH4's normal protective role.

Certainty Assessment:

- **BH4 Elevation:** Moderate certainty (consistent across two studies, statistically significant, mechanistic depth)
- **Sample Size:** Small (2023: n=32 general CFS, n=10 CFS+OI; 2024: n=10 ME+OI) — pilot studies only
- **Replication:** Same research group (Peterson, Roy, Gottschalk); needs independent validation
- **Mechanism:** Low-moderate certainty (in vitro validation, but n=10 very small; mechanism needs in vivo confirmation)
- **Clinical Utility:** Low certainty (not yet validated as biomarker; no established cutoffs; therapeutic direction unclear)
- **Generalizability:** OI subgroup only; unclear if applies to broader ME/CFS population or is specific to orthostatic intolerance regardless of underlying disease
- **Limitations:** Very small samples, single research group, BH4 paradox unresolved, cross-sectional design, no longitudinal tracking, therapeutic implications unknown

Research Priorities: High-priority validation needed: (1) Independent replication in larger cohort (n>100), (2) Clarification of BH4 paradox (why is normally-beneficial BH4 elevated and apparently harmful?), (3) BH4/BH2 ratio analysis, (4) Longitudinal tracking to assess stability as biomarker, (5) Correlation with objective measures of orthostatic intolerance (tilt table, CPET), (6) In vivo confirmation of microglial iNOS activation. Therapeutic trials should NOT proceed until mechanism is clarified and direction determined (supplement vs reduce).

H.13 Exercise Physiology and Post-Exertional Malaise

Full Citation: Franklin JD, Graham M, the Workwell Foundation. The Prospects of the Two-Day Cardiopulmonary Exercise Test (CPET) in ME/CFS Patients: A Meta-Analysis. *International Journal of Environmental Research and Public Health*. 2020;17(24):9575.

DOI: [10.3390/ijerph17249575](https://doi.org/10.3390/ijerph17249575)

PMCID: PMC7765094

Key Findings: Day 2 CPET shows decreased VO₂max and workload unique to ME/CFS.

DOI: [10.3390/jcm9124040](https://doi.org/10.3390/jcm9124040)

PMID: 33327624

PMCID: PMC7765094

Published: December 14, 2020

Study Design: Meta-analysis of two-day CPET studies in ME/CFS

Key Findings: Meta-analysis of 5 studies (n=98 ME/CFS, n=51 controls) demonstrating that the second-day CPET shows significantly reduced oxygen consumption, workload, and peak heart rate compared to day 1, which is pathognomonic for ME/CFS. Post-exertional reduction in VO₂max provides objective biomarker for post-exertional malaise. Day 2 impairment correlates with symptom severity.

Relevance: Landmark meta-analysis establishing two-day CPET as best-validated objective test for PEM in ME/CFS. Provides quantitative evidence that PEM is a real physiological phenomenon, not deconditioning or psychological. Essential reference for understanding exercise intolerance in ME/CFS.

Certainty: High (systematic meta-analysis, reproducible findings, consistent across included studies, published open-access in *Journal of Clinical Medicine*).

Full Citation: Keller BA, Receno CN, Franconi CJ, et al. Cardiopulmonary and Metabolic Responses During a 2-Day CPET in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: Translating Reduced Oxygen Consumption to Impairment Status to Treatment Considerations. *Journal of Translational Medicine*. 2024;22(1):627.

DOI: [10.1186/s12967-024-05410-5](https://doi.org/10.1186/s12967-024-05410-5)

PMID: 38965566

PMCID: PMC11229500

Published: July 5, 2024

Study Design: Cross-sectional mechanistic study with 2-day CPET

Sample Size: ME/CFS patients (n unspecified in abstract; full sample available in published manuscript)

Key Findings: Two-day CPET demonstrates: (1) reduced peak VO₂ on day 2 vs day 1; (2) chronotropic incompetence with inadequate heart rate response to exercise; (3) metabolic abnormalities including reduced oxygen utilization efficiency; (4) anaerobic threshold changes suggesting mitochondrial dysfunction; (5) correlation between CPET impairment and objective disability metrics. First study to directly link reduced oxygen consumption on 2-day CPET to standardized impairment ratings and treatment decision-making.

Relevance: Provides translational framework connecting two-day CPET findings to clinical disability assessment and guide therapeutic interventions. Demonstrates that reduced VO₂ is not deconditioning but reflects true metabolic/mitochondrial dysfunction. Critical for understanding exercise intolerance mechanisms in ME/CFS.

Certainty: High (recent peer-reviewed study in *Journal of Translational Medicine*, mechanistic detail, published with supplementary data; builds on established CPET methodology).

Full Citation: Two-day cardiopulmonary exercise testing in long COVID post-exertional malaise diagnosis. *Respiratory Medicine and Research*. 2024;85:101551.

DOI: [10.1016/j.resmer.2024.101551](https://doi.org/10.1016/j.resmer.2024.101551)

Full Citation: Recovery time from two-day CPET in ME/CFS. Cornell Center for Enervating NeuroImmune Disease. 2024.

URL: <https://neuroimmune.cornell.edu/news/recovery-from-two-day-cpet-in-me-cfs/>

Key Findings: Recovery ~13 days in ME/CFS vs ~2 days in sedentary controls.

H.14 Treatment Evidence

H.14.1 Immunological Therapies: Rituximab and Cyclophosphamide

Fluge et al. 2019 — Rituximab Phase III Trial (NEGATIVE)

Full Citation: Fluge Ø, Rekeland IG, Lien K, et al. B-Lymphocyte Depletion in Patients With Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: A Randomized, Double-Blind, Placebo-Controlled Trial. *Annals of Internal Medicine*. 2019;170(9):585–593.

DOI: [10.7326/M18-1451](https://doi.org/10.7326/M18-1451)

PMID: 30934066

Trial Registration: ClinicalTrials.gov NCT02229942

Study Design: Phase III randomized, double-blind, placebo-controlled, multicenter trial

Sample Size: 151 patients (77 rituximab, 74 placebo)

Key Findings: This trial was **NEGATIVE**. Overall response rates were 35.1% in the placebo group versus 26.0% in the rituximab group (difference 9.2 percentage points [95% CI: –5.5 to 23.3]; $p = 0.22$). The treatment groups showed no differences in fatigue scores over 24

months (difference in average score 0.02 [CI: -0.27 to 0.31]; $p = 0.80$) or any secondary endpoints (SF-36, physical function, activity levels). Serious adverse events occurred in 26.0% of rituximab patients versus 18.9% of placebo patients. Notably, the placebo response rate of 35% demonstrates substantial natural fluctuation or expectation effects in ME/CFS.

Relevance: This landmark negative trial definitively refutes B-cell depletion as a therapeutic strategy for ME/CFS, contradicting earlier promising Phase II open-label studies from the same research group. The high placebo response rate (35%) has critical implications for trial design: it demonstrates that even large apparent improvements in uncontrolled studies may not represent true drug effects. The study serves as a cautionary tale about extrapolating from small early-phase trials and emphasizes the necessity of rigorous placebo-controlled validation. **Rituximab should NOT be used for ME/CFS.**

Certainty Assessment:

- **Quality:** High (Phase III RCT, double-blind, placebo-controlled, multicenter, published in *Annals of Internal Medicine*)
- **Sample:** $n=151$ (adequate for Phase III efficacy trial)
- **Replication:** This *was* the replication—contradicted earlier positive Phase II results from same group
- **Funding:** Publicly funded (Norwegian Research Council, health trusts), no industry bias
- **Limitations:** Self-reported outcomes (though standard for ME/CFS); possible heterogeneity (small subset might respond but undetectable in overall analysis)

Rekeland et al. 2024 — 6-Year Follow-up

Full Citation: Rekeland IG, Sørland K, Neteland LL, et al. Six-year follow-up of participants in two clinical trials of rituximab or cyclophosphamide in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *PLoS One*. 2024;19(7):e0307484.

DOI: [10.1371/journal.pone.0307484](https://doi.org/10.1371/journal.pone.0307484)

PMID: 39042627

PMCID: PMC11265720

Study Type: Long-term observational follow-up of RituxME (Phase III RCT) and CycloME (Phase II open-label) trials

Key Findings: At 6-year follow-up, rituximab showed no sustained benefit over placebo: 27.6% of rituximab-treated patients achieved SF-36 Physical Function ≥ 70 compared to 20.4% of placebo patients (not statistically significant). In contrast, the open-label cyclophosphamide group showed 44.1% achieving SF-36 PF ≥ 70 , with 17.6% reaching normal function (PF ≥ 90). However, the authors explicitly caution: “cyclophosphamide carries toxicity concerns and should not be used for ME/CFS patients outside clinical trials.” The placebo group data

provides valuable natural history information: approximately 20% of patients improved substantially over 6 years without specific treatment, while 15% worsened significantly.

Relevance: Confirms long-term lack of benefit for rituximab. The cyclophosphamide results are intriguing but **cannot be interpreted as evidence of efficacy** due to absence of placebo control, open-label design, small sample (n=34 at 6 years), and potential selection bias (94% follow-up rate may favor responders). Given cyclophosphamide's severe toxicity (cancer risk, infertility, life-threatening infections), the uncertain benefit based solely on open-label data is insufficient to justify clinical use. The findings do, however, support the hypothesis of a possible immune-mediated subgroup and warrant investigation of safer immune-modulating agents with proper placebo-controlled trials.

Certainty Assessment:

- **Rituximab data:** High certainty of lack of benefit (follow-up of rigorous RCT)
- **Cyclophosphamide data:** Low certainty (no placebo control, open-label, small sample, selection bias)
- **Natural history data:** Moderate certainty (from placebo arm, but 24% loss to follow-up)
- **Limitations:** Cyclophosphamide findings are hypothesis-generating only; different patient populations between trials complicate cross-comparison

H.14.2 H2 Receptor Antagonists: Cimetidine

Goldstein 1986 — Historical Clinical Observations

Full Citation: Goldstein JA. Cimetidine, ranitidine, and Epstein-Barr virus infection. *Annals of Internal Medicine*. 1986;105(1):139.

DOI: [10.7326/0003-4819-105-1-139_2](https://doi.org/10.7326/0003-4819-105-1-139_2)

PMID: 3013060

Publication Type: Letter to the editor

Key Findings: Early clinical report suggesting H2 receptor antagonists (cimetidine/ranitidine) might benefit ME/CFS patients with Epstein-Barr virus reactivation. Goldstein reported “positive results in 90% of cases of mononucleosis treated with Tagamet,” with rapid symptom resolution (within 24 hours in acute cases). Treatment approach was extended to chronic fatigue syndrome patients based on success in acute EBV infection. Proposed mechanism: H2 receptor blockade reduces suppressor T cell function, thereby enhancing cell-mediated immunity against viral infections.

Relevance: Establishes historical precedent for H2 antagonist use in CFS and provides mechanistic rationale for immunomodulation via suppressor T cell blockade. Clinical experience suggests potential responder subgroup (EBV-driven cases), with rare but dramatic responses reported (1–2% of patients based on subsequent clinical experience). However, evidence quality is insufficient for general recommendations—published only as brief letter without controlled data, objective outcome measures, or standardized patient selection criteria. Notable limitation: tolerance development reported with long-term use. The paper represents hypothesis-driven clinical innovation typical of 1980s CFS treatment exploration during peak interest in “chronic Epstein-Barr virus syndrome.”

Certainty Assessment:

- **Quality:** Very Low (letter/case series, no controlled design, no blinding)
- **Sample:** Not specified in original letter; anecdotal reports only
- **Replication:** Limited; concept explored in broader immunomodulation literature but not specifically validated for ME/CFS
- **Limitations:** No controlled trial, subjective outcomes, patient selection unclear, no standardized dosing protocol, published 1986 with limited methodology; concept based on 1980s understanding of “suppressor T cells” (terminology now outdated, though mechanism remains plausible with modern understanding of regulatory T cells)

Modern Context: Recent evidence suggests **two distinct mechanisms** may contribute to cimetidine benefit: (1) immune modulation via H2 receptor blockade (Goldstein’s proposed mechanism), and (2) pharmacokinetic enhancement of concurrent antiviral therapy (see Stuijt 2026 below). The rare dramatic responders may represent patients with active viral reactivation and either excessive regulatory T cell function or subtherapeutic antiviral drug levels.

Stuijt et al. 2026 — Pharmacokinetic Enhancement of Antivirals

Full Citation: Stuijt R, et al. Use of cimetidine to enhance systemic acyclovir concentrations in patients with ineffective suppressive therapy for recurring herpes simplex virus infections: A novel purpose for an old drug. *British Journal of Clinical Pharmacology*. 2026.

DOI: [10.1002/bcp.70313](https://doi.org/10.1002/bcp.70313)

Publication Type: Case series

Year: 2026 (most recent evidence)

Key Findings: Cimetidine increases systemic acyclovir concentrations through competitive inhibition of renal tubular secretion (OCT2/MATE1 transporters). Patients with recurrent herpes simplex virus infections who failed standard valacyclovir suppressive therapy had confirmed subtherapeutic acyclovir plasma levels. After valacyclovir dose escalation, or in some patients only after concomitant prescription of cimetidine, adequate acyclovir levels were achieved with “significant clinical improvement.” Earlier pharmacokinetic studies quantified

the effect: cimetidine co-administration increases valacyclovir AUC by 73% and acyclovir AUC by 27%. The pharmacokinetic modifications did not affect tolerability of valacyclovir.

Relevance: Provides recent clinical evidence (2026) for a **second mechanism** of cimetidine benefit distinct from Goldstein's immune modulation hypothesis. Pharmacokinetic enhancement may explain treatment failures in ME/CFS patients on valacyclovir for suspected viral reactivation—subtherapeutic drug levels could result from variable absorption, metabolism, or high renal clearance. Cimetidine offers cost-effective strategy to boost antiviral efficacy without dose escalation, potentially with better tolerability. However, evidence is specific to HSV; extrapolation to EBV and other herpesviruses in ME/CFS remains uncertain. Therapeutic drug monitoring would ideally guide this approach but is not widely available for acyclovir.

Certainty Assessment:

- **Pharmacokinetics:** High certainty (well-established inhibition of renal secretion, quantified in controlled studies)
- **Clinical benefit in HSV:** Low-Medium certainty (case series, very recent publication awaiting independent replication)
- **Application to ME/CFS:** Low certainty (no ME/CFS-specific studies; mechanistic extrapolation only)
- **Limitations:** Case series design (no controls, selection bias), HSV-specific evidence, therapeutic drug monitoring not widely available, optimal cimetidine dose for this indication not established, long-term safety unknown for chronic combination therapy

Clinical Integration: The combination of Goldstein's immune modulation mechanism (1986) and Stuijt's pharmacokinetic enhancement mechanism (2026) suggests **dual potential pathways** for cimetidine benefit in ME/CFS:

- **Patients on antivirals:** Pharmacokinetic boost likely primary mechanism (increased drug levels)
- **Patients without antivirals:** Immune modulation may be primary mechanism (enhanced cell-mediated immunity)
- **Combination therapy:** Synergistic effects possible when both mechanisms operative

Simons et al. 2019 — Comprehensive Immunomodulation Review

Full Citation: Simons FER, Rawat A, Simons KJ. Immunomodulatory properties of cimetidine: Its therapeutic potentials for treatment of immune-related diseases. *International Immunopharmacology*. 2019;68:8–18.

DOI: [10.1016/j.intimp.2018.12.061](https://doi.org/10.1016/j.intimp.2018.12.061)

PMID: 30802678

Publication Type: Comprehensive review article

Key Findings: Systematic review of cimetidine's immunomodulatory properties beyond acid suppression. Cimetidine exerts powerful effects on both innate and adaptive immune systems: reduces regulatory/suppressor T cell-mediated immunosuppression, has powerful stimulatory effects on CD8⁺ cytotoxic T cells, enhances cell-mediated immunity markers (increased response to skin-test antigens, lymphocyte mitogen stimulation), and modulates cytokine production (affects IL-2, IL-15, IL-1 β). H2 receptors are differentially expressed: H1R predominantly on Th1 cells, H2R predominantly on Th2 cells and regulatory T cells. H2 blockade shifts balance toward Th1/cell-mediated immunity. Therapeutic applications investigated include viral infections (herpesviruses, viral warts), vaccine adjuvant properties, and immune-mediated conditions.

Relevance: Provides mechanistic validation for Goldstein's clinical observations with modern immunological understanding. While immunomodulatory effects are well-documented in controlled studies, **clinical translation to ME/CFS remains unvalidated**. The gap between mechanistic understanding and clinical evidence remains significant—most therapeutic applications lack rigorous controlled trials. Review identifies ME/CFS as potential application based on immune dysfunction hypothesis and viral reactivation, but notes absence of controlled evidence. Supports hypothesis of possible responder subgroup (patients with excessive immunosuppression, viral reactivation, T cell dysfunction), but does not provide guidance on patient selection or biomarker-based stratification.

Certainty Assessment:

- **Mechanistic Understanding:** Medium-High (well-characterized immunological effects, consistent across multiple studies)
- **Clinical Translation:** Weak (most applications lack controlled trials in disease populations)
- **ME/CFS Efficacy:** Very Low (mentioned as potential application, no ME/CFS-specific controlled evidence)
- **Limitations:** Synthesizes heterogeneous study designs; many applications based on mechanistic reasoning without clinical validation; optimal dosing for immunomodulation unclear; long-term safety for immunological indications not established

Clinical Summary and Evidence Synthesis Overall Certainty for ME/CFS: VERY LOW (case series, historical reports, mechanistic studies; no controlled trials)

Responder Phenotype: Clinical experience suggests only 1–2% of patients experience dramatic benefit, likely representing specific subgroup with:

- Active herpesvirus reactivation (EBV, HHV-6) as primary driver
- Subtherapeutic antiviral drug levels (if on concurrent therapy)
- Excessive regulatory/suppressor T cell activity
- Possible MCAS overlap (histamine-mediated symptoms)

Dual Mechanisms: Two distinct pathways may contribute:

1. **Pharmacokinetic:** Increases acyclovir/valacyclovir levels (Stuijt 2026; certainty: HIGH for mechanism, LOW for ME/CFS application)
2. **Immunomodulatory:** Enhances cell-mediated immunity via H2 blockade (Goldstein 1986, Simons 2019; certainty: MEDIUM for mechanism, VERY LOW for ME/CFS efficacy)

Safety Considerations:

- Drug interaction potential: Cimetidine inhibits multiple CYP450 enzymes (extensive interactions with other medications)
- Alternative H2 antagonists: Famotidine has fewer drug interactions, may be safer for chronic use
- Tolerance development: Effectiveness may decrease over time with continued use
- Long-term hormonal effects: Gynecomastia, sexual dysfunction rare but documented
- Not recommended for chronic use without physician supervision

Research Gaps:

- No controlled trials in ME/CFS populations
- No biomarker studies to identify responder phenotype
- Optimal dosing and duration unclear
- Mechanism validation needed with modern immunological methods
- Comparison studies with other H2 antagonists (famotidine vs. cimetidine)
- Combination protocols with antivirals need systematic evaluation

Critical Evidence Gap: No randomized controlled trials of cimetidine in ME/CFS exist. All evidence is from case series (Goldstein 1986; Stuijt 2026), mechanistic studies in other conditions (immune modulation in cancer and EBV), and pharmacokinetic studies (Soul-Lawton 2001 drug interactions). Application to ME/CFS remains hypothesis-driven without controlled validation. The observed clinical responses in case series could reflect placebo effects, natural disease fluctuation, or benefits from concurrent interventions rather than cimetidine-specific effects.

Clinical Recommendations:

- **NOT recommended** as first-line or general treatment (evidence insufficient)
- May be considered for treatment-refractory patients with:
 - Confirmed viral reactivation (EBV, HHV-6, CMV)
 - Failed antiviral monotherapy
 - Documented T cell abnormalities
- Requires physician supervision due to drug interaction potential
- Consider famotidine as alternative (fewer interactions)
- Ideally combined with therapeutic drug monitoring if on concurrent antivirals
- Controlled trials urgently needed to validate efficacy and identify responders

H.14.3 Low-Dose Naltrexone

Polo et al. 2019 — Retrospective Observational Study

Full Citation: Polo O, Pesonen P, Tuominen E. Low-dose naltrexone in the treatment of myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). *Fatigue: Biomedicine, Health & Behavior*. 2019;7(4):207–217.

DOI: [10.1080/21641846.2019.1692770](https://doi.org/10.1080/21641846.2019.1692770)

Published: November 19, 2019

Study Design: Retrospective chart review

Sample Size: 218 ME/CFS patients

Key Findings: In this large retrospective analysis, 73.9% (n=161/218) of ME/CFS patients reported subjective improvement with low-dose naltrexone (3.0–4.5 mg/day) over mean 1.7-year follow-up. Specific improvements included vigilance/alertness (51.4%), physical performance (23.9%), and cognitive function (21.1%). No severe adverse events were reported; mild transient side effects (insomnia, nausea) occurred at treatment initiation but typically resolved. The authors explicitly acknowledge the study's limitations, concluding: "placebo-controlled studies are needed to confirm these findings."

Relevance: This is the largest observational study of LDN in ME/CFS, suggesting potential benefit with an excellent safety profile. However, **the absence of placebo control is a critical limitation**. Given that the rituximab trial demonstrated 35% placebo response, the 74% response rate to LDN in an open-label setting cannot be assumed to represent true drug effect. Additional concerns include retrospective design, subjective outcomes, selection bias (which patients were prescribed LDN?), and lack of validated outcome measures. That said, LDN's favorable safety profile, low cost (generic), and mechanistic plausibility (opioid receptor modulation, immune effects) make it a high-priority candidate for rigorous placebo-controlled RCT testing. Given the contrast with rituximab (both looked promising in early studies; rituximab failed RCT), this study should be viewed as hypothesis-generating rather than evidence of efficacy.

Certainty Assessment:

- **Safety:** High certainty (large sample, long follow-up, no serious adverse events)
- **Efficacy:** Low certainty (no placebo control, retrospective design, subjective outcomes)
- **Clinical Use:** May be reasonable for treatment-refractory patients with informed consent about uncertain evidence
- **Research Priority:** High (safe, cheap, worth rigorous RCT validation)
- **Limitations:** Retrospective, no placebo control (disqualifying for efficacy claims), undefined response criteria, no standardized dosing, single geographic location (Finland)

H.14.4 Sleep Medications: Dual Orexin Receptor Antagonists

St Onge et al. 2022 — Daridorexant Phase 3 Efficacy Review

Full Citation: St Onge E, Phillips B, Rowe C. Daridorexant: A New Dual Orexin Receptor Antagonist for Insomnia. *J Pharm Technol.* 2022;38(5):297–303.

DOI: [10.1177/87551225221112546](https://doi.org/10.1177/87551225221112546)

PMID: 36035587

PMCID: PMC9420920

Study Design: Phase 3 clinical trial review

Sample Size: n=1,854 (Phase 3 combined)

Key Findings: Daridorexant is a dual orexin receptor antagonist (DORA) FDA-approved for insomnia in January 2022. Unlike benzodiazepines and z-drugs that enhance GABA-A receptor activity, daridorexant blocks orexin signaling to reduce wakefulness while preserving natural sleep architecture. At 50 mg: wake after sleep onset (WASO) decreased by 18.3 minutes, latency to persistent sleep (LPS) decreased by 11.7 minutes at month 3 (both $p < 0.0001$ vs placebo). Critically, daridorexant **improved daytime functioning with no residual sedation**. The 25 mg dose also showed efficacy, supporting flexible dosing.

Safety Profile: Adverse events were mild (fatigue, nasopharyngitis, headache), serious events <2%, **no withdrawal symptoms or rebound insomnia** upon discontinuation. No tolerance development observed. Importantly, no respiratory depression (unlike GABA-A agonists), making it safer for medically complex patients.

Certainty Assessment:

- **Quality:** High (Phase 3 RCTs, FDA approval, peer-reviewed)
- **Sample:** n=1,854 (adequate power)
- **Replication:** Multiple Phase 3 trials with consistent findings
- **Limitations:** No direct ME/CFS trials (insomnia population); limited head-to-head comparison data
- **ME/CFS Applicability:** High (off-label, but safety profile ideal for patients who cannot afford daytime impairment)

Kunz et al. 2022 — 52-Week Long-Term Safety

Full Citation: Kunz D, Dauvilliers Y, Benes H, et al. Long-Term Safety and Tolerability of Daridorexant in Patients with Insomnia Disorder. *CNS Drugs.* 2022;37(1):93–106.

DOI: [10.1007/s40263-022-00980-8](https://doi.org/10.1007/s40263-022-00980-8)

PMID: 36529837

PMCID: PMC9829592

Study Design: 52-week open-label extension study

Sample Size: n=801

Key Findings: Over 52 weeks of continuous use: treatment-emergent adverse events 35–40%, with 91.2% mild-to-moderate. **No withdrawal, rebound insomnia, or tolerance development.** Improved morning alertness (not residual sedation). Safe in medically complex patients: 72.1% had comorbidities, 64.8% on polypharmacy. Falls: 1.1–2.7% with no somnolence during incidents.

Relevance to ME/CFS: The long-term safety profile is critical for ME/CFS patients requiring chronic sleep support. Traditional sedatives cause tolerance (dose escalation), dependence (withdrawal syndrome), cognitive impairment, and next-day sedation—all problematic for patients already experiencing severe fatigue and cognitive dysfunction. Daridorexant avoids these issues, making it suitable for long-term use in chronic illness populations.

López-Amador 2025 — Orexin Dysfunction in ME/CFS

Full Citation: López-Amador N. An integrative review on the orexin system and hypothalamic dysfunction in myalgic encephalomyelitis/chronic fatigue syndrome: implications for precision medicine. *Explor Neurol Ther.* 2025;5:1004112.

DOI: [10.37349/ent.2025.1004112](https://doi.org/10.37349/ent.2025.1004112)

Study Type: Integrative review

Sample: 27 studies reviewed

Key Findings: Consistent evidence of **reduced orexin-A levels in ME/CFS** across multiple studies. Variable orexin-B responses suggest biomarker potential for subtyping. Review proposes DORAs may ameliorate both sleep AND fatigue symptoms by targeting documented hypothalamic dysfunction. **No ME/CFS trials yet**—recommends controlled trials as high research priority.

Clinical Synthesis: DORAs represent a mechanistically-informed treatment option for ME/CFS sleep disturbances:

1. **Mechanism targets ME/CFS pathology:** Orexin dysfunction documented in ME/CFS; DORAs modulate this system
2. **Dual symptom targeting:** May improve both sleep AND fatigue (two core symptoms)
3. **Superior safety profile:** No hangover, no tolerance, no withdrawal—critical for chronic use
4. **Preserved cognition:** No next-day cognitive impairment (unlike GABA-A agonists)
5. **Evidence quality:** High for general insomnia; Medium for ME/CFS application (mechanistic rationale strong, but disease-specific trials needed)

Comparison to Traditional Sleep Aids:

Issue	Traditional Sedatives	DORAs (Daridorexant)
Tolerance	Yes (dose escalation)	No (sustained efficacy)
Dependence	Yes (withdrawal)	No (safe discontinuation)
Rebound insomnia	Yes	No
Cognitive impairment	Yes	No
Hangover/sedation	Yes	No (improved alertness)
Sleep architecture	Altered (↓ REM/SWS)	Preserved
Fall risk	Elevated	Low (1–2%)

H.14.5 Mitochondrial and Metabolic Support: Amino Acids

Rationale for Multi-Amino Acid Approach ME/CFS is characterized by documented metabolic and mitochondrial dysfunction, including deficiencies in specific amino acids and TCA/urea cycle intermediates. Evidence supports a **comprehensive multi-amino acid approach** rather than single-agent supplementation.

Myhill et al. 2009 — Mitochondrial Dysfunction Biomarker

Full Citation: Myhill S, Booth NE, McLaren-Howard J. Chronic fatigue syndrome and mitochondrial dysfunction. *Int J Clin Exp Med*. 2009;2(1):1–16.

PMID: 19436827

PMCID: PMC2680051

Study Design: Case-control with ATP profile testing

Sample Size: n=71 ME/CFS patients, 53 controls

Key Findings: Using the ATP Profile test (measuring ATP levels, ADP-to-ATP conversion efficiency, and mitochondrial membrane integrity), **98.6% of ME/CFS patients showed measurable mitochondrial dysfunction**. The degree of dysfunction correlated with symptom severity ($p < 0.001$). This established objective biomarker evidence for the metabolic hypothesis of ME/CFS.

Yamano et al. 2016 — TCA and Urea Cycle Deficiencies

Full Citation: Yamano E, Sugimoto M, Hirayama A, et al. Index markers of chronic fatigue syndrome with dysfunction of TCA and urea cycles. *Scientific Reports*. 2016;6:34990.

DOI: [10.1038/srep34990](https://doi.org/10.1038/srep34990)

PMID: 27725700

PMCID: PMC5057083

Study Design: Comprehensive metabolomics (plasma)

Sample Size: n=133 ME/CFS patients, 66 healthy controls

Key Findings: Rigorous metabolomic analysis revealed **significantly decreased plasma concentrations** of:

- **Citrulline** (urea cycle intermediate, NO precursor)
- **Malate** (TCA cycle intermediate, ATP production)
- **Isocitrate, citrate** (TCA cycle)

Diagnostic markers: pyruvate/isocitrate ratio and ornithine/citrulline ratio distinguished ME/CFS from controls with high sensitivity/specificity. Published in *Nature Scientific Reports*—high methodological quality.

Relevance: Provides direct biochemical evidence for TCA cycle and urea cycle dysfunction in ME/CFS, supporting supplementation with citrulline-malate to restore these metabolic pathways.

Shungu et al. 2012 — Brain Glutathione Deficiency

Full Citation: Shungu DC, Weiduschat N, Murrrough JW, et al. Increased ventricular lactate in chronic fatigue syndrome. III. Relationships to cortical glutathione and clinical symptoms implicate oxidative stress in disorder pathophysiology. *NMR in Biomedicine*. 2012;25(9):1073–1087.

DOI: [10.1002/nbm.2772](https://doi.org/10.1002/nbm.2772)

PMID: 22281935

PMCID: PMC3896083

Study Design: MRS brain imaging with pilot intervention

Sample Size: n=15 ME/CFS patients, 15 controls

Key Findings: Magnetic resonance spectroscopy (MRS) demonstrated **significantly reduced cortical glutathione** in ME/CFS compared to controls. Glutathione levels correlated strongly with physical functioning ($\rho = 0.506$) and energy ($\rho = 0.606$), both $p < 0.001$. **Pilot intervention:** 1800 mg/day N-acetylcysteine (NAC) for 4 weeks normalized brain glutathione, ventricular lactate, AND clinical symptoms.

Relevance: Provides direct brain imaging evidence for oxidative stress and glutathione deficiency in ME/CFS, with pilot data supporting NAC supplementation. An NINDS trial is ongoing testing 900 mg vs 3600 mg/day NAC.

Myhill et al. 2012 — Clinical Audit of Comprehensive Protocol

Full Citation: Myhill S, Booth NE, McLaren-Howard J. Targeting mitochondrial dysfunction in the treatment of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) – a clinical audit. *Int J Clin Exp Med*. 2012;6(1):1–15.

PMID: 23289015

PMCID: PMC3523104

Study Design: Clinical audit with biomarker monitoring

Sample Size: n=30 compliant patients (of 67 total)

Key Findings: Comprehensive mitochondrial support protocol including amino acids (L-carnitine), CoQ10, magnesium, B vitamins, and D-ribose produced **4-fold improvement in ATP Profile scores** in compliant patients. Non-compliant patients showed no improvement, supporting causality. Protocol also required dietary modification (low-carb, whole foods), sleep optimization, and pacing.

Certainty Assessment:

- **Quality:** Medium (clinical audit, not RCT, but with objective biomarkers)
- **Replication:** Consistent with metabolomic studies (Yamano, Shungu)
- **Limitations:** Single clinic, self-selected adherent population, no placebo control
- **Implication:** Comprehensive approach validated; isolated component efficacy unknown

Ogawa et al. 1998 — L-Arginine Alone Insufficient

Full Citation: Ogawa R, Toyama S, Yamamoto Y. L-arginine fails to enhance natural killer activity in chronic fatigue syndrome. *International Journal of Molecular Medicine*. 1998;2(6):735–739.

DOI: [10.3892/ijmm.2.6.735](https://doi.org/10.3892/ijmm.2.6.735)

PMID: 9850744

Study Design: In vitro NK cell stimulation

Sample Size: n=20 (10 CFS, 10 controls)

Key Findings: L-arginine enhanced NK cell activity in healthy controls but **failed to enhance NK activity in CFS patients**, despite normal NO synthase gene expression. This indicates pathway dysfunction rather than substrate deficiency—supplementation alone insufficient without addressing downstream issues.

Relevance: **Critical finding:** Single amino acid supplementation (arginine alone) does not work in ME/CFS. Multiple deficiencies require multiple interventions. L-citrulline (bypasses hepatic first-pass, more effectively raises arginine levels) combined with cofactors may be more effective.

Evidence-Based Amino Acid Protocol Based on the above literature, a comprehensive approach includes:

Core Components (High Certainty for Deficiency):

1. **N-Acetylcysteine (NAC):** 1800 mg/day (600 mg TID) — restores glutathione, pilot efficacy data
2. **L-Citrulline-Malate:** 6–8 g/day — addresses documented TCA/urea cycle deficiencies
3. **L-Carnitine:** 1000–1500 mg/day — mitochondrial fatty acid transport (contraindicated in hypothyroidism)

Essential Cofactors:

- Magnesium: 400–600 mg/day (glycinate or malate forms)
- Coenzyme Q10: 100–300 mg/day (ubiquinol form preferred)
- B-complex vitamins (especially B3, B12)
- D-ribose: 5–15 g/day (ATP precursor)

Targeted Additions:

- **L-Lysine:** 1000–2000 mg/day during viral reactivation only (competes with arginine for viral replication)
- **L-Arginine:** Only in combination with citrulline (not as monotherapy)

Safety Considerations:

- L-Carnitine contraindicated in hypothyroidism/Hashimoto's
- L-Lysine: caution with cardiovascular disease, not for indefinite use
- NAC: GI effects common initially; FDA-approved drug with established safety
- Start low, go slow: test individual tolerance before full dosing

Certainty Summary:

- **Metabolic deficiencies:** HIGH certainty (rigorous metabolomics, MRS imaging)
- **Single amino acid efficacy:** LOW (arginine alone failed)
- **Comprehensive protocol efficacy:** MEDIUM (clinical audit with biomarkers, needs RCT)
- **NAC specifically:** MEDIUM-HIGH (pilot data positive, RCT ongoing)

Research Gaps:

- No RCTs of individual amino acids in ME/CFS
- Factorial designs needed to determine essential components
- Optimal dosing and duration unclear
- Biomarker-guided personalization not validated

H.14.6 Antiviral Therapy: Valacyclovir and Valganciclovir

Rationale for Antiviral Treatment ME/CFS frequently follows viral infections, and evidence suggests persistent viral reactivation (particularly EBV, HHV-6, CMV) in subsets of patients. Antiviral therapy targets these potential viral drivers.

Lerner et al. 2002–2007 — Valacyclovir for EBV Subset

Full Citation: Lerner AM, Beqaj SH, Deeter RG, Fitzgerald JT. Valacyclovir treatment in Epstein-Barr virus subset chronic fatigue syndrome: thirty-six months follow-up. *In Vivo*. 2007;21(5):707–713.

PMID: 18019402

Earlier Study: Lerner AM, Beqaj SH, Deeter RG, et al. A six-month trial of valacyclovir in the Epstein-Barr virus subset of chronic fatigue syndrome: improvement in left ventricular function. *Drugs Today*. 2002;38(8):549–561.

PMID: 12582420

Study Design: Open-label trials with cardiac function monitoring

Key Findings: CFS patients with EBV-persistent infection (EBV single-virus subset) improved after 6 months of continuous valacyclovir dosing. Importantly, **CFS patients with EBV/cytomegalovirus co-infection did not benefit**—valacyclovir is not effective against CMV. Specific improvements included left ventricular function (measured by echocardiography) and subjective symptom reduction. Thirty-six month follow-up showed sustained benefit in the EBV-only subset.

Montoya et al. 2013 — Valganciclovir Randomized Trial

Full Citation: Montoya JG, Kogelnik AM, Bhangoo M, et al. Randomized clinical trial to evaluate the efficacy and safety of valganciclovir in a subset of patients with chronic fatigue syndrome. *Journal of Medical Virology*. 2013;85(12):2101–2109.

DOI: [10.1002/jmv.23713](https://doi.org/10.1002/jmv.23713)

PMID: 23959519

Study Design: Randomized, double-blind, placebo-controlled trial

Sample Size: n=30 (20 VGCV, 10 placebo)

Duration: 6 months treatment

Key Findings: Thirty CFS patients with elevated IgG antibody titers against HHV-6 and EBV were randomized 2:1 to valganciclovir (VGCV) or placebo. Statistically significant improvements observed in:

- Mental fatigue subscore ($p = 0.039$)
- Fatigue Severity Scale score ($p = 0.006$)
- Cognitive function ($p = 0.025$)

VGCV patients were **7.4 times more likely to be classified as responders** ($p = 0.029$). Improvements began within the first 3 months and were maintained. Retrospective chart review of 61 patients showed 52% response rate, with longer treatment associated with improved response ($p = 0.0002$).

Recent Developments (2024–2025) The Bateman Horne Center tested valacyclovir combined with celecoxib (anti-inflammatory) for Long COVID fatigue:

- Low-dose group (750 mg valacyclovir + celecoxib): Meaningful fatigue reduction
- High-dose group (1,500 mg valacyclovir + celecoxib): More GI side effects, less benefit
- Results suggest combination anti-inflammatory + antiviral approach may be promising

Certainty Assessment:

- **Quality:** Medium (one small RCT, multiple open-label studies)
- **Sample:** Small ($n=30$ for RCT)
- **Replication:** Consistent findings across Lerner and Montoya groups
- **Critical caveat:** Benefit limited to patients with documented viral reactivation (elevated antibody titers)
- **CMV caveat:** Valacyclovir ineffective for CMV co-infection; valganciclovir needed
- **Clinical use:** Reasonable for biomarker-selected patients (elevated EBV/HHV-6 titers); NOT for unselected ME/CFS population

H.14.7 Palmitoylethanolamide (PEA)

Overview Palmitoylethanolamide (PEA) is an endogenous fatty acid amide with anti-inflammatory, analgesic, and mast cell-stabilizing properties. It acts primarily through PPAR- α activation and has emerging evidence for ME/CFS and related conditions.

Mechanism of Action

- **PPAR- α agonist:** Activates peroxisome proliferator-activated receptor alpha, reducing inflammatory gene expression
- **Mast cell stabilization:** Reduces mast cell degranulation and histamine release
- **Endocannabinoid modulation:** Enhances anandamide signaling without direct CB receptor activation
- **Neuroinflammation:** Reduces glial activation and neuroinflammatory markers

Clinical Evidence

Patient-Reported Outcomes (PNAS 2025): A study of >3,900 ME/CFS and Long COVID patients found PEA had a 41.5% positive response rate in patient-reported outcomes.

Pain Efficacy: Spanish 2025 review confirms PEA effective for nociceptive, neuropathic, and nociplastic pain, with effects typically appearing after 4–6 weeks.

Clinical Experience: At IIMEC 2024, Dr. Jesper Mehlsen reported approximately 600–700 patients (of >1,000) in his clinic taking PEA, with some reporting “I can’t live without PEA.”

Dosing:

- Standard dose: 600–1200 mg/day
- Higher doses (1200 mg/day) more effective for chronic pain
- Ultramicronized forms (um-PEA) have better bioavailability, allowing lower doses
- Effects typically require 4–6 weeks to manifest

Certainty Assessment:

- **Quality:** Medium (patient-reported outcomes, clinical experience, mechanistic studies)
- **ME/CFS-specific trials:** None published
- **Safety:** Excellent (endogenous compound, well-tolerated)
- **Rationale:** Strong mechanistic basis for MCAS/inflammation/pain management
- **Clinical use:** Reasonable as adjunct for pain, inflammation, or MCAS symptoms

H.14.8 D-Ribose

Teitelbaum et al. 2006 — Pilot Study

Full Citation: Teitelbaum JE, Johnson C, St Cyr J. The use of D-ribose in chronic fatigue syndrome and fibromyalgia: a pilot study. *J Altern Complement Med.* 2006;12(9):857–862.

DOI: [10.1089/acm.2006.12.857](https://doi.org/10.1089/acm.2006.12.857)

PMID: 17109576

Study Design: Open-label pilot study

Sample Size: n=41 (FMS and/or CFS patients)

Intervention: 5 g D-ribose three times daily

Key Findings: D-ribose resulted in significant improvement across all five visual analog scale (VAS) categories: energy, sleep, mental clarity, pain intensity, and well-being. Additionally:

- 66% of patients experienced significant improvement
- Average energy increase: 45%

- Average well-being improvement: 30%
- Well-tolerated with minimal side effects

Larger Multicenter Study: A subsequent multicenter study enrolled 257 patients across 53 US clinics, confirming the pilot findings with similar improvements in fatigue, sleep, cognitive function, and overall well-being.

Mechanism: D-ribose is a pentose sugar essential for ATP synthesis. In ME/CFS:

- ATP recycling is impaired (slow ADP → ATP conversion)
- D-ribose levels decline during low-oxygen states
- Supplementation provides substrate for de novo ATP synthesis
- Works synergistically with other mitochondrial supports (CoQ10, carnitine, magnesium)

Dosing: 5 g three times daily (15 g/day total). Effects may be seen within days. Continue at this dose while improvement continues, then consider maintenance dosing. Best combined with comprehensive mitochondrial support protocol.

Certainty Assessment:

- **Quality:** Low-Medium (open-label studies only, no RCTs)
- **Sample:** Adequate (257 in multicenter study)
- **Replication:** Consistent across two studies
- **Mechanistic support:** Strong (ATP metabolism well-understood)
- **Limitations:** No placebo control, potential for placebo effect
- **Clinical use:** Reasonable as part of mitochondrial support; safe, inexpensive

H.14.9 Low-Dose Aripiprazole (LDA)

Crosby et al. 2021 — Stanford Retrospective Study

Full Citation: Crosby LD, Kalanidhi S, Engel A, et al. Off label use of Aripiprazole shows promise as a treatment for Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS): a retrospective study of 101 patients treated with a low dose of Aripiprazole. *J Transl Med.* 2021;19(1):50.

DOI: [10.1186/s12967-021-02721-9](https://doi.org/10.1186/s12967-021-02721-9)

PMID: 33536023

PMCID: PMC7860172

Study Design: Retrospective chart review

Sample Size: n=101 ME/CFS patients

Setting: Stanford University

Key Findings: Of 101 patients taking low-dose aripiprazole (0.2–2.0 mg/day, mean 1.1 mg/-day):

- **74% (75/101)** experienced improvement in one or more categories
- Fatigue score improved by -2.89 units ($p < 0.001$)
- Brain fog improved by -2.33 units ($p < 0.001$)
- Unrefreshing sleep improved by -2.05 units ($p < 0.001$)
- PEM frequency reduced from every 4.2 days to every 8.3 days
- 18 patients reported complete resolution of PEM
- 6 patients able to return to work
- 12% no response; 14% discontinued due to side effects

Mechanism: At standard doses (10–30 mg), aripiprazole inhibits dopamine. At **low doses (0.2–2 mg)**, it acts as a dopamine agonist (“dopamine stabilizer”). Proposed mechanisms for ME/CFS benefit:

- D2 receptor partial agonism may reduce neuroinflammation
- Modulation of microglial activation
- Enhanced dopaminergic tone in reward/motivation circuits

Dosing: Start at 0.25 mg/day; titrate based on response and tolerability up to maximum 2 mg/day. Compounding pharmacies needed for doses below 1 mg (standard tablets are 2 mg+).

Certainty Assessment:

- **Quality:** Low-Medium (retrospective, no control group)
- **Sample:** Adequate ($n=101$)
- **Replication:** None (single study)
- **Limitations:** Retrospective design, no placebo control, selection bias, atypical antipsychotic class
- **Safety concerns:** Metabolic effects (weight gain, glucose dysregulation) even at low doses; requires monitoring
- **Clinical use:** Consider for treatment-refractory patients with informed consent about uncertain evidence and need for metabolic monitoring

H.14.10 Autonomic Dysfunction: Ivabradine and Pyridostigmine

Ivabradine for POTS

Drug Class: Selective If (funny channel) inhibitor

FDA Approval: Heart failure (off-label for POTS)

Mechanism: Reduces heart rate without affecting blood pressure (unlike beta-blockers)

Recent Evidence (2025): A 2025 study in the Journal of Cardiovascular Pharmacology found ivabradine treatment significantly reduced:

- Change in heart rate with standing (Δ HR): from 40 (30–70) to 15 (8–19) bpm
- Malmö symptom score: from 86 to 39 ($p = 0.005$)
- Strong correlation between Δ HR reduction and symptom improvement ($R = +0.828$)

Systematic Review (2025): A systematic review in Clinical Autonomic Research examined POTS treatment with special focus on ME/CFS comorbidity. Ivabradine and midodrine demonstrated the highest rates of symptomatic improvement among medications studied. 67–100% of patients showed symptomatic benefit across studies.

Certainty Assessment:

- **Quality:** Low-Medium (small studies, mostly observational)
- **Efficacy:** Consistent heart rate reduction and symptom improvement
- **Advantage over beta-blockers:** No blood pressure reduction, less fatigue
- **ME/CFS applicability:** High (30–40% of ME/CFS patients have POTS)
- **Clinical use:** First-line consideration for ME/CFS patients with documented POTS

Pyridostigmine (Mestinon)

Drug Class: Acetylcholinesterase inhibitor

FDA Approval: Myasthenia gravis (off-label for POTS/ME/CFS)

Mechanism: Increases acetylcholine, enhances parasympathetic tone, improves venous return

Systrom et al. 2022 — Randomized Controlled Trial

Full Citation: Joseph P, Arevalo C, Engel AG, et al. Neurovascular Dysregulation and Acute Exercise Intolerance in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: A Randomized, Placebo-Controlled Trial of Pyridostigmine. *Chest*. 2022;162(5):1116–1126.

DOI: [10.1016/j.chest.2022.04.146](https://doi.org/10.1016/j.chest.2022.04.146)

PMID: 35526605

Study Design: Single-center, randomized, double-blind, placebo-controlled

Sample Size: n=45 ME/CFS patients

Key Findings: Patients received 60 mg pyridostigmine or placebo between two invasive cardiopulmonary exercise tests (iCPET):

- Peak VO₂ **increased after pyridostigmine but decreased after placebo**
- Pyridostigmine improved cardiac output and right ventricular filling pressures
- Worsening after placebo may signal onset of PEM
- Supports hypothesis that **treatable neurovascular dysregulation** underlies acute exercise intolerance

Clinical Experience: Grubb reported 43% of 203 POTS patients (51% of those tolerating the drug) experienced benefit. Most commonly improved: fatigue (55%), palpitations (60%), presyncope (60%), syncope (48%).

Dosing: Start 30 mg once daily; increase to 30 mg 2–3 times daily as tolerated. Common side effects include GI upset, muscle cramps, increased salivation. Caution in asthmatics (increases bronchial secretions).

Certainty Assessment:

- **Quality:** Medium-High (RCT with objective outcomes)
- **Sample:** Adequate (n=45)
- **Mechanistic:** Objective improvement in cardiac output and oxygen uptake
- **Clinical applicability:** High for patients with exercise intolerance and preload failure
- **Limitations:** Single-dose acute study; long-term efficacy not established in RCT

H.14.11 Graded Exercise Therapy (Negative Evidence)

Full Citation: Geraghty K, Hann M, Kurtev S. The Updated NICE Guidance Exposed the Serious Flaws in CBT and Graded Exercise Therapy Trials for ME/CFS. *Healthcare*. 2022;10(5):898.

DOI: [10.3390/healthcare10050898](https://doi.org/10.3390/healthcare10050898)

PMCID: PMC9141828

Key Findings: Methodological flaws and biases in trials; patient surveys show harm from GET.

Full Citation: Vink M, Vink-Niese A. The PACE Trial's GET Manual for Therapists Exposes the Fixed Incremental Nature of Graded Exercise Therapy for ME/CFS. *Life*. 2025;15(4):584.

PMID: 32568149

H.14.12 Neuromodulation: Transcutaneous Vagus Nerve Stimulation

Natelson et al. 2022 — tVNS for Long COVID-ME/CFS (Pilot)

Full Citation: Natelson BH, Vu T, Mao X, Soto O, Stegner A, Yamamoto Y, Scherl E, Togo F, Lange G. Transcutaneous Vagus Nerve Stimulation in the Treatment of Long COVID- Chronic Fatigue Syndrome. *medRxiv*. 2022. doi:10.1101/2022.11.08.22281807

DOI: [10.1101/2022.11.08.22281807](https://doi.org/10.1101/2022.11.08.22281807)

Publication Status: Preprint (not peer-reviewed)

Study Design: Open-label pilot study (no sham control)

Sample Size: n=14 completers (16 enrolled)

Population: Long COVID patients meeting 1994 CFS case definition criteria

Intervention: Parasymp tVNS device, left tragus placement, 35+ minutes daily for 6 weeks

Key Findings: 8 of 14 patients (57%) met success criteria (improvement on ≥ 2 of 4 outcome measures: SF-36 physical function $\geq 14\%$ improvement, symptom severity VAS reduction ≥ 2 points, loss of “fatigue case” status on Chalder scale, or Patient Global Impression of Change +2/+3). No adverse effects reported during the 6-week trial. The 57% response rate exceeds typical ME/CFS placebo response (24%) but causality cannot be established without sham control.

Relevance: First pilot study of tVNS specifically for ME/CFS (Long COVID subset). Suggests potential benefit through vagal nerve modulation of autonomic and immune function. The intervention is low-cost, non-invasive, home-based, and well-tolerated, making it suitable for severe ME/CFS patients. However, the open-label design and small sample size limit interpretability.

Certainty Assessment:

- **Quality:** Low to Medium (open-label pilot, small n, no sham control, preprint status)
- **Sample:** n=14 (very small)
- **Replication:** None (single study, no independent replication)
- **Conflicts:** Device donated by manufacturer; study funded by patient donations
- **Limitations:** Cannot rule out placebo effect; no mechanistic biomarkers measured; patient-adjusted intensity (no standardized parameters); no follow-up data on durability
- **Clinical Recommendation:** Preliminary evidence only; requires sham-controlled RCT validation before clinical adoption

Yu et al. 2022 — tVNS for POTS (Provides Mechanistic Context)

Full Citation: Yu L, Huang B, Po SS, et al. Transdermal auricular vagus stimulation for the treatment of postural tachycardia syndrome. *Autonomic Neuroscience: Basic and Clinical*. 2022;243:103021.

DOI: [10.1016/j.autneu.2021.103021](https://doi.org/10.1016/j.autneu.2021.103021)

PMID: 35183906

Study Type: Narrative review synthesizing multiple tVNS studies in POTS

Relevance to ME/CFS: POTS affects 30–40% of ME/CFS patients; shared autonomic dysfunction mechanisms

Key Findings: **Acute effects (n=14, randomized crossover):** Significant improvement in tilt test tolerance time ($+5.3 \pm 2.6$ min, $p=0.0156$) and reduced orthostatic symptom scores. **Chronic effects (n=9, open-label, 2 weeks):** Significant reductions in COMPASS-31 total score and orthostatic intolerance domain (both $p<0.05$). **Mechanisms:** (1) Autonomic rebalancing (improved heart rate variability), (2) Reduction of β 1-adrenergic receptor and α 1-AR autoantibodies (significant in active vs sham), (3) Decreased serum TNF- α levels, (4) Activation of cholinergic anti-inflammatory pathway via α 7 nicotinic acetylcholine receptors on macrophages. **Responder phenotype:** Patients with low baseline vagal modulation (high-frequency HRV <200 ms²) showed greatest improvement.

Relevance: Provides mechanistic rationale for tVNS in ME/CFS through POTS studies. Both autonomic rebalancing and anti-inflammatory effects are relevant to ME/CFS pathophysiology. Adrenergic receptor autoantibodies and elevated TNF- α are also reported in ME/CFS subgroups, suggesting therapeutic overlap. However, efficacy is established specifically for POTS; extrapolation to ME/CFS without POTS requires validation.

Protocol Parameters: Cymba conchae stimulation, 25–50 Hz frequency, 200–300 microsecond pulse width, subsensory to tolerated current (typically <2 mA), 30-second on/off duty cycle, 4 hours daily for chronic protocols. Baseline HRV testing may identify likely responders.

Certainty Assessment:

- **Quality (for POTS):** Medium (includes randomized crossover but chronic study lacks sham control)
- **Sample:** Small (n=9–14)
- **Replication:** Multiple studies but same research group
- **Limitations:** Short duration (2 weeks chronic); small samples; single research group; POTS-specific population
- **ME/CFS Applicability:** Medium (shared pathophysiology, high POTS comorbidity) to Low (no direct ME/CFS validation beyond Natelson pilot)
- **Clinical Recommendation:** Evidence-based for ME/CFS patients with documented POTS; investigational for broader ME/CFS application

Integration Notes: tVNS represents a potential non-pharmacological, home-based intervention for autonomic and immune modulation in ME/CFS. The dual mechanisms (vagal tone enhancement + cholinergic anti-inflammatory pathway) address multiple pathophysiological features. Safety profile is favorable with minimal adverse effects across studies. However, current evidence is preliminary: the ME/CFS pilot lacks sham control, and POTS studies have small samples and short durations. Baseline autonomic testing (HRV) may enable precision medicine approach by identifying likely responders. Larger sham-controlled RCTs in ME/CFS populations are needed before clinical adoption beyond POTS subgroup.

H.19 Mast Cell Activation and Antihistamine Therapies

H.19.1 Hardcastle et al. 2016 — Mast Cell Phenotype Abnormalities in ME/CFS

Full Citation: Hardcastle SL, Brenu EW, Johnston S, et al. Novel characterisation of mast cell phenotypes from peripheral blood mononuclear cells in chronic fatigue syndrome/myalgic encephalomyelitis patients. *BMC Immunology*. 2016;17(1):30.

DOI: [10.1186/s12865-016-0167-z](https://doi.org/10.1186/s12865-016-0167-z)

PMID: 27362406

PMCID: PMC4928291

Published: June 29, 2016

Study Design: Cross-sectional immunophenotyping study

Sample Size: 18 ME/CFS patients (12 moderate, 6 severe), 13 matched healthy controls

Key Findings:

- Significant increase in naïve mast cells (CD117⁺CD34⁺FcεRI⁺chymase⁺) in moderate and severe ME/CFS ($p < 0.05$)
- Elevated CD40 ligand and MHC-II receptors on differentiated mast cells in severe ME/CFS
- Demonstrates measurable mast cell abnormalities at cellular level
- Supports hypothesis that mast cells may be involved in ME/CFS pathophysiology

Certainty: High (well-designed study, statistically significant findings)

Clinical Relevance: Provides biological basis for mast cell involvement in ME/CFS; supports rationale for mast cell-targeted therapies

H.19.2 Wirth & Scheibenbogen 2023 — Mast Cell Activation and Vascular Pathomechanisms

Full Citation: Wirth K, Scheibenbogen C. Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) and Comorbidities: Linked by Vascular Pathomechanisms and Vasoactive Mediators? *Healthcare*. 2023;11(7):978.

DOI: [10.3390/healthcare11070978](https://doi.org/10.3390/healthcare11070978)

PMID: 37046903

PMCID: PMC10224216

Published: March 27, 2023

Study Type: Review and hypothesis paper

Key Mechanisms:

- Mast cell activation shares pathogenic mechanisms with ME/CFS through excessive histamine, heparin, prostaglandins, leukotrienes, and protease release
- Spillover of vasoactive mediators into systemic circulation worsens orthostatic intolerance via histamine's vascular effects
- β_2 -adrenergic receptor dysfunction amplifies symptoms
- ME/CFS patients with MCAS and orthostatic intolerance reported symptom alleviation significantly more often following mast cell-targeted treatment ($p < 0.0001$)

Certainty: Medium (mechanistic hypothesis with clinical correlation)

Clinical Relevance: Links mast cell activation to orthostatic intolerance; suggests mast cell-targeted therapies may benefit subset of ME/CFS patients with vascular/autonomic symptoms

H.19.3 Novak et al. 2022 — Mast Cell Disorders, Cerebral Hypoperfusion, and Small Fiber Neuropathy

Full Citation: Novak P, Giannetti MP, Weller E, Hamilton MJ, Castells M. Mast cell disorders are associated with decreased cerebral blood flow and small fiber neuropathy. *Ann Allergy Asthma Immunol.* 2022;128(3):299–306.e1.

DOI: [10.1016/j.anai.2021.10.006](https://doi.org/10.1016/j.anai.2021.10.006)

PMID: 34648976

Published: March 2022

Study Design: Case-control study with objective neurological measurements

Sample Size: 15 hereditary alpha tryptasemia (H α T), 16 mast cell activation syndrome (MCAS), 14 matched controls

Key Findings:

- **Small fiber neuropathy highly prevalent:** 80% of H α T and 81% of MCAS patients (vs controls, $p < 0.001$)
- **Cerebral hypoperfusion during orthostatic stress:** CBFv reduced $-24.2 \pm 14.3\%$ in H α T, $-20.8 \pm 5.5\%$ in MCAS (vs controls $+2.3 \pm 8.1\%$, $p < 0.001$)
- **Universal dysautonomia:** All patients showed abnormalities when sympathetic, parasympathetic, and sudomotor tests combined
- Similar outcomes despite different tryptase levels (H α T: 14.3 ± 2.5 ng/mL vs MCAS: 3.8 ± 1.8 ng/mL) — suggests common final pathway

Certainty: High (objective measurements, rigorous protocols, appropriate controls)

Clinical Relevance: **Critical for ME/CFS** — provides objective biomarkers for mast cell-mediated neurological dysfunction. The 80% SFN prevalence, cerebral hypoperfusion, and dysautonomia mirror ME/CFS findings, suggesting MCAS screening in ME/CFS patients with severe orthostatic intolerance. Testable via autonomic testing battery, transcranial Doppler, and skin biopsy.

H.19.4 Magadmi et al. 2019 — CADM1-Mediated Mast Cell-Nerve Adhesion Amplifies Inflammation

Full Citation: Magadmi R, Meszaros J, Damanhoury ZA, Seward EP. CADM1-dependent adhesion between mast cells and sensory neurons enhances mast cell inflammatory responses. *Front Cell Neurosci.* 2019;13:262.

DOI: [10.3389/fncel.2019.00262](https://doi.org/10.3389/fncel.2019.00262)

Published: 2019

Study Design: In vitro mechanistic study (mouse cells)

Key Findings:

- CADM1 protein mediates physical adhesion between mast cells and sensory neurons
- Neuronal contact amplifies mast cell degranulation (2-fold) and IL-6 secretion (3-fold)
- Blocking CADM1 abolished enhancement — demonstrates adhesion requirement
- Effect is neuron-specific (HEK 293 cells expressing CADM1 did not replicate) — suggests additional neuronal signals
- TNF α unchanged — indicates selective pathway modulation

Certainty: Medium (well-controlled in vitro study, but mouse cells; awaits human and in vivo validation)

Clinical Relevance: Provides mechanistic support for “signal amplifier hypothesis” of mast cell-nerve interactions in ME/CFS. Could explain pain amplification disproportionate to tissue damage and the connection between mast cell activation and small fiber neuropathy documented in Novak et al. 2022.

H.19.5 Nakamura et al. 2014 — Circadian Clock Regulates Mast Cell Function

Full Citation: Nakamura Y, Nakano N, Ishimaru K, et al. Circadian regulation of allergic reactions by the mast cell clock in mice. *J Allergy Clin Immunol.* 2014;133(2):568–575.

DOI: [10.1016/j.jaci.2013.07.040](https://doi.org/10.1016/j.jaci.2013.07.040)

PMID: 24060274

Published: February 2014

Study Design: Genetic mouse model with circadian clock manipulation

Key Findings:

- Mast cells possess intrinsic circadian clocks that drive time-of-day variation in degranulation
- *Clock* gene mutation abolished temporal variation in IgE-mediated responses (both in vivo and in vitro)
- Fc ϵ RI receptor expression and signaling show circadian rhythms in wild-type cells, lost in *Clock*-mutant
- Adrenalectomy disrupts mast cell clock rhythms — demonstrates adrenal hormones entrain mast cell clocks

Certainty: High for mechanism (elegant genetics, replicated); Low-Medium for ME/CFS relevance (extrapolation from mouse allergy model)

Clinical Relevance: Provides basis for “temporal priming hypothesis” — HPA axis dysfunction in ME/CFS could disrupt mast cell circadian regulation, leading to inappropriate

activation timing. May explain symptom timing patterns, sleep-symptom interactions, and potential for chronotherapy (timing mast cell treatments to peak reactivity periods).

H.19.6 Steinberg et al. 1996 — Terfenadine Trial (Negative)

Full Citation: Steinberg P, McNutt BE, Marshall P, et al. A double-blind placebo-controlled study of the efficacy of oral terfenadine in the chronic fatigue syndrome. *J Allergy Clin Immunol.* 1996;97(1 Pt 1):119–126.

DOI: [10.1016/S0091-6749\(96\)80212-6](https://doi.org/10.1016/S0091-6749(96)80212-6)

PMID: 8568124

Published: January 1996

Study Design: Double-blind, placebo-controlled RCT

Sample Size: 30 CFS patients enrolled, 28 completed

Intervention: Terfenadine 60 mg twice daily for 8 weeks (H1 antihistamine only)

Results: • **NO therapeutic benefit detected**

- No improvement in symptom amelioration
- No improvement in physical or social functioning
- No improvement in health perceptions or mental health
- Additional finding: 73% had atopy, 53% had positive immediate skin test results

Conclusion: “Terfenadine is unlikely to be of clinical benefit in treating CFS symptoms”

Certainty: High (well-designed RCT with negative results)

Clinical Implications: H1 antihistamine alone insufficient; suggests combination therapy (H1+H2 or H1+mast cell stabilizer) may be necessary

H.19.7 Davis et al. 2023 — Long COVID Case with H1/H2 Combination Success

Full Citation: Davis HE, McCorkell L, Vogel JM, Topol EJ. Case Study of ME/CFS Care Applied to Long COVID: Hypothesis Regarding Exercise Intolerance, Orthostatic Intolerance, Mast Cell Activation, Sleep Dysfunction, Neuropathy, and Viral Persistence. *Healthcare.* 2023;11(6):896.

DOI: [10.3390/healthcare11060896](https://doi.org/10.3390/healthcare11060896)

PMID: 36981567

PMCID: PMC10048325

Published: March 21, 2023

Study Type: Single case report (n=1)

Patient: Long COVID patient meeting ME/CFS criteria

Interventions and Outcomes: • **H1 blockers** (loratadine 10 mg OR fexofenadine 180 mg): “helpful with energy and cognitive dysfunction”

- **H2 blocker** (famotidine 40 mg BID): “helpful with energy and cognitive dysfunction”

- **Discontinuation test:** Stopping fexofenadine and famotidine → “increased fatigue and increased cognitive dysfunction, both of which improved rapidly upon re-sumption”
- **Cromolyn** (400 mg QID): Peak heart rate during walking fell from 130–140 bpm to 100–105 bpm
- **Quercetin** (1000 mg BID): “Improvement in fatigue and allergic symptoms”

Certainty: Low (n=1 case report, but dramatic response with discontinuation-rechallenge confirmation)

Clinical Relevance: Demonstrates potential for H1+H2 combination therapy; suggests mast cell-targeted approach may benefit post-viral fatigue syndromes

H.19.8 Theoharides et al. 2012 — Quercetin Superior to Cromolyn

Full Citation: Theoharides TC, Asadi S, Panagiotidou S. Quercetin in combination with IL-6 inhibits histamine and TNF release from mast cells through interaction with the IL-6 receptor. *PLOS ONE*. 2012;7(3):e33805.

DOI: [10.1371/journal.pone.0033805](https://doi.org/10.1371/journal.pone.0033805)

PMID: 22470478

PMCID: PMC3314669

Published: March 29, 2012

Study Design: In vitro comparison + clinical pilot trials

Concentration: Quercetin 100 μ M (approximated by 2 g/day oral dosing)

Key Findings:

- **IgE/Anti-IgE stimulation:** Quercetin inhibited histamine (82% vs 67%), PGD₂ (77% vs 75%), leukotrienes (99% vs 88%) comparably to cromolyn
- **Substance P stimulation:** Quercetin dramatically outperformed cromolyn — IL-8 reduced from 437.2 to 115.4 pg/mL (quercetin) vs 362.9 pg/mL (cromolyn)
- **Mechanism:** Quercetin worked prophylactically (30 min pre-stimulus); cromolyn required simultaneous addition
- **Clinical trial — Contact dermatitis:** Quercetin 2 g/day for 3 days reduced nickel patch reactions >50% in 8 of 10 patients; pruritus eliminated completely
- **Clinical trial — Photosensitivity:** Quercetin 1 g increased minimal erythema dose in all patients ($p=0.002$)

Certainty: Medium-High (strong in vitro data, pilot clinical success)

Clinical Relevance: Quercetin may be superior to prescription cromolyn for mast cell stabilization; available over-the-counter; well-tolerated

H.19.9 Clemons et al. 2011 — Amitriptyline Mast Cell Inhibition

Full Citation: Clemons A, Vasiadi M, Kempuraj D, et al. Amitriptyline and prochlorperazine inhibit proinflammatory mediator release from human mast cells: possible relevance to chronic fatigue syndrome. *J Clin Psychopharmacol*. 2011;31(3):385–387.

DOI: [10.1097/JCP.0b013e3182196e50](https://doi.org/10.1097/JCP.0b013e3182196e50)

PMID: 21532369

PMCID: PMC3498825

Published: June 2011

Study Design: In vitro study on human mast cells

Key Findings:

- Amitriptyline (AMI) and prochlorperazine (PRO) at 25 μ M significantly reduced IL-8, VEGF, and IL-6 release from stimulated human mast cells
- Bupropion, citalopram, and atomoxetine did NOT inhibit mast cells
- Mechanism involves modulation of intracellular calcium (FURA2 AM calcium indicator assays)
- AMI inhibits histamine release while permitting serotonin release

Conclusion: “The ability of amitriptyline, but not other antidepressants, to inhibit human mast cell release of pro-inflammatory cytokines may be relevant to their apparent benefit in CFS”

Certainty: Medium (mechanistic in vitro study, explains clinical observations)

Clinical Relevance: Amitriptyline’s benefit in ME/CFS may involve mast cell inhibition beyond pain/sleep effects; specific pharmacological mechanism

H.19.10 Rupatadine — Dual H1/PAF Antagonist with Mast Cell Stabilization

Full Citations:

- Piñero-González J, et al. Rupatadine inhibits proinflammatory mediator secretion from human mast cells triggered by different stimuli. *J Investig Allergol Clin Immunol.* 2017;27(3):161–168. PMID: 19672095; PMCID: PMC7065400.

- Mullol J, Bousquet J, Bachert C, et al. Rupatadine in allergic rhinitis and chronic urticaria. *Allergy.* 2008;63(Suppl 87):5–28. PMID: 18339040.

Mechanism: Triple action — (1) H1 receptor antagonist, (2) PAF (platelet-activating factor) antagonist, (3) Direct mast cell stabilizer

Mast Cell Effects:

- Rupatadine (10–50 μ M) inhibited IL-8 (80%), VEGF (73%), histamine (88%) release from LAD2 mast cell line
- Also inhibited IL-6, IL-8, IL-10, IL-13, and TNF release from human cord blood-derived cultured mast cells
- More effective than levocetirizine and desloratadine at PAF-induced mast cell inhibition

PAF Antagonism Potency:

- Rupatadine IC₅₀ = 4.6 μ M (most potent)
- Loratadine IC₅₀ = 142 μ M (~31× less potent)
- Cetirizine IC₅₀ >200 μ M (>43× less potent)
- Fexofenadine IC₅₀ >200 μ M (>43× less potent)

Efficacy Ranking: Network meta-analysis for allergic rhinitis (SUCRA scores):

- Rupatadine 20 mg: 99.7% (highest rank)
- Rupatadine 10 mg: 76.3%
- Fexofenadine, cetirizine: moderate
- Loratadine 10 mg: lowest (inferior to all others)

Certainty: High (multiple RCTs, network meta-analysis, in vitro mechanistic data)

Clinical Relevance: Superior to standard H1 antihistamines; unique PAF antagonism may

benefit ME/CFS patients with mast cell activation and vascular/orthostatic symptoms

Note: PAF is a key inflammatory mediator in ME/CFS contributing to vascular leakage, brain fog, and orthostatic issues

H.19.11 Moldofsky et al. 2015 — Ketotifen in Fibromyalgia (Negative)

Full Citation: Moldofsky H, Harris HW, Archambault WT, Kwong T, Lederman S. A randomized, double-blind, placebo-controlled Phase 1 trial of ketotifen in fibromyalgia. *J Rheumatol.* 2015;42(12):2505–2513.

DOI: [10.3899/jrheum.150460](https://doi.org/10.3899/jrheum.150460)

PMID: 26472411

PMCID: PMC4417653

Published: December 2015

Study Design: Phase 1 RCT, double-blind, placebo-controlled

Sample Size: 51 fibromyalgia patients (24 ketotifen, 27 placebo)

Intervention: Ketotifen 2 mg BID for 8 weeks (after 1-week titration)

Results: NO significant differences in primary outcomes:

- Pain intensity: ketotifen −1.3 vs placebo −1.5 ($p=0.7$)
- FIQR scores: −12.1 vs −12.2 ($p=0.9$)
- Side effect: Transient sedation 28.6% vs 4%

Certainty: High (well-designed RCT showing no benefit)

Clinical Relevance: Mast cell stabilization alone may not address core pathophysiology in central pain syndromes like fibromyalgia; relevance to ME/CFS unclear

Note: Despite this negative finding, retrospective ME/CFS study (not included here) showed 77% of continuers had significant PEM reduction with ketotifen

H.20 Severe ME/CFS: Assessment Methodology

H.20.1 Fricke et al. 2026 — ACHTSAM Study Protocol

Full Citation: Fricke C, Deibert P, Maier P, Kern W, Krumnau O, Barsch F. ACHTSAM study protocol: outreach diagnostics and assessment of tolerability in severe ME/CFS—a pilot study. *BMJ Open.* 2026;16(3):e113095. [[104](#)]

DOI: [10.1136/bmjopen-2025-113095](https://doi.org/10.1136/bmjopen-2025-113095)

Trial Registration: DRKS00035231; FRKS005506

Study Design: Prospective, non-interventional observational pilot study with home-based outreach assessments.

Population: $n=25$ patients with severe to very severe ME/CFS (Bell score ≤ 30), University Medical Centre Freiburg, Germany.

Key Innovation: First systematic investigation of which diagnostic procedures can be safely and tolerably administered to severe and very severe ME/CFS patients in their home

environment. Addresses the critical gap that >60% of severe ME/CFS patients cannot complete standard inpatient diagnostic protocols.

Assessment Battery:

- **Phase 1:** Validated remote questionnaires (Composite Autonomic Score-31, Short Form 12, DePaul Symptom Questionnaire-PEM, Munich Berlin Symptom Questionnaire, Fatigue Life Experience Inventory)
- **Phase 2a:** Home visits for resting ECG, HRV with paced breathing, pupillography, cognitive assessments (MoCA, TMT-B, SDMT), osteosonography, body composition, blood sampling, salivary cortisol
- **Phase 2b:** Near-infrared spectroscopy (NIRS) for muscle oxygenation, neurocognitive/psychological assessment, handgrip dynamometry, Schellong test, EndoPAT endothelial function, salivary cortisol

Primary Hypotheses:

- H1: <50% of standard clinical assessments will be fully completable due to PEM or exhaustion
- H2: Non-invasive supine-position assessments will have ≥80% completion; high-burden tests <30%
- H3: Very severe patients (Bell ≤20) will tolerate ≥20% fewer assessments than severe (Bell 21–30)
- H4: Autonomic, endothelial, and pupillary parameters will show deviations in a substantial proportion

Significance: Establishes methodological framework for inclusive severe ME/CFS research; home-based approach reduces clinic-induced stress and PEM risk; includes pilot biobank component for future biomarker investigations (viral reactivation, autoantibodies).

Limitations: Study protocol only (results pending April 2026); small sample ($n=25$); no control group; geographically restricted to 50 km radius of Freiburg; sequential assessment design precludes attribution of PEM to individual procedures.

Certainty: N/A (protocol paper; certainty will depend on results).

Relevance: Directly addresses systematic exclusion of severe patients from ME/CFS research (Sections 5.3.9 and 5.3); informs future trial design for this underserved population.

H.20.2 Zuberbier et al. 2022 — EAACI/GA²LEN Urticaria Guideline (Fourfold Up-Dosing)

Full Citation: Zuberbier T, Abdul Latiff AH, Abuzakouk M, et al. The international EAACI/GA²LEN/EuroGuiDerm/APAAACI guideline for the definition, classification, diagnosis, and management of urticaria. *Allergy*. 2022;77(3):734–766.

DOI: [10.1111/all.15090](https://doi.org/10.1111/all.15090)

PMID: 34536239

Published: March 2022

Study Type: International evidence-based clinical guideline

Key Recommendations:

- Step 1: Standard-dose second-generation H1 antihistamine
- Step 2: Up to **fourfold dose** of the same second-generation H1 antihistamine (if inadequate after 2–4 weeks)
- Step 3: Add-on therapy (omalizumab, cyclosporine, or other agents)

- Recommendation applies class-wide to all second-generation H1 antihistamines

Certainty: High (multi-society guideline with formal evidence grading)

Clinical Relevance: Provides the formal basis for higher-than-standard antihistamine dosing adopted by MCAS specialists. Developed for chronic spontaneous urticaria (CSU), but extrapolated to MCAS based on shared histamine-mediated pathophysiology. See Section 22.11.

H.20.3 van den Elzen et al. 2017 — Antihistamine Up-Dosing Safety

Full Citation: van den Elzen MT, van Os-Medendorp H, van den Brink I, et al. Effectiveness and safety of antihistamines up to fourfold or higher in treatment of chronic spontaneous urticaria. *Clinical and Translational Allergy*. 2017;7:4.

DOI: [10.1186/s13601-017-0141-3](https://doi.org/10.1186/s13601-017-0141-3)

PMID: 28228950

PMCID: PMC5309999

Published: February 2017

Study Design: Retrospective cohort study

Sample Size: 171 patients; 59 received above-fourfold doses (median 8×, range 5–12× standard)

Key Findings: • Only 10% of patients at above-fourfold doses reported side effects (predominantly somnolence)

- No serious adverse events at any dose level
- 62% of patients at standard dose were uncontrolled; 45% responded to dose increase

Certainty: Medium (retrospective, single-center, but largest dataset on high-dose safety)

Clinical Relevance: Provides reassurance for dose escalation beyond standard in MCAS patients. Key safety data supporting Section 22.11.

H.20.4 Podder et al. 2023 — Up-Dosing Efficacy Review

Full Citation: Podder I, Dhabal A, Chakraborty SS. Efficacy and Safety of Up-dosed Second-generation Antihistamines in Uncontrolled Chronic Spontaneous Urticaria: A Review. *Journal of Clinical and Aesthetic Dermatology*. 2023;16(3):44–50.

PMCID: [PMC10027330](https://pubmed.ncbi.nlm.nih.gov/PMC10027330/)

Published: March 2023

Study Type: Systematic review of up-dosing trials

Key Findings: • Fexofenadine: 83% responder rate at up-dosing (highest among all antihistamines studied) — Grade A recommendation

- Cetirizine/levocetirizine: 54% responder rate — Grade A recommendation
- Desloratadine: 30% responder rate at 4× — Grade B recommendation
- Drowsiness increases (9.5–59%) but no dose-dependent systemic complications

Certainty: High (systematic review with evidence grading)

Clinical Relevance: Provides drug-specific efficacy data for choosing which H1 antihistamine to up-dose. Fexofenadine emerges as the most effective candidate for escalation.

H.20.5 Salvucci et al. 2023 — Antihistamines in Long COVID

Full Citation: Salvucci F, Codella R, Coppola A, et al. Antihistamines improve cardiovascular manifestations and other symptoms of long-COVID attributed to mast cell activation. *Frontiers in Cardiovascular Medicine*. 2023;10:1202696.

DOI: [10.3389/fcvm.2023.1202696](https://doi.org/10.3389/fcvm.2023.1202696)

PMCID: PMC10388239

Published: July 2023

Study Design: Prospective observational study

Sample Size: 14 long-COVID patients with MCAS features

Intervention: Fexofenadine 180 mg + famotidine 40 mg daily for 20 days

Key Findings: • 29% complete symptom disappearance

- Fatigue resolved in 43%
- Brain fog resolved in 43%
- Tachycardia resolved in 57%

Certainty: Low-Medium (small sample, no control group, short treatment duration)

Clinical Relevance: Provides preliminary evidence for H1+H2 combination in post-viral fatigue with MCAS features. Supports antihistamine trial in ME/CFS patients with mast cell activation phenotype.

H.20.6 Molderings et al. 2016 — MCAS Pharmacological Treatment Options

Full Citation: Molderings GJ, Haenisch B, Bogdanow M, Fimmers R, Nöthen MM. Pharmacological treatment options for mast cell activation disease. *Naunyn-Schmiedeberg's Archives of Pharmacology*. 2016;389(7):671–694.

DOI: [10.1007/s00210-016-1247-1](https://doi.org/10.1007/s00210-016-1247-1)

PMID: 27132234

PMCID: PMC4903110

Published: July 2016

Study Type: Comprehensive pharmacological review

Key Content: • Systematic review of all pharmacological interventions for MCAS

- H1 and H2 antihistamine dose escalation strategies
- Mast cell stabilizers, leukotriene inhibitors, and biologics
- Treatment algorithm based on clinical response

Certainty: Medium (expert review; limited by sparse RCT evidence for MCAS)

Clinical Relevance: Primary reference for MCAS pharmacotherapy. Supports stepwise antihistamine escalation approach used in Section [22.11.4](#).

H.20.7 Nurmatov et al. 2015 — H1 Antihistamines in Mast Cell Activation (Systematic Review)

Full Citation: Nurmatov UB, Rhatigan E, Simons FER, Sheikh A. H1-antihistamines for primary mast cell activation syndromes: a systematic review. *Allergy*. 2015;70(9):1052–1061.

DOI: [10.1111/all.12672](https://doi.org/10.1111/all.12672)

PMID: 26095756

Published: September 2015

Study Design: Systematic review

Key Findings:

- Only 5 small, mostly historical trials identified for H1 antihistamines in primary mast cell activation syndromes
- Evidence base is extremely limited
- Highlights major gap between widespread clinical use and formal trial evidence

Certainty: High (rigorous systematic review methodology)

Clinical Relevance: Documents the evidence gap underlying MCAS antihistamine dosing. Fourfold up-dosing recommendation is extrapolated from CSU guidelines, not supported by MCAS-specific trials.

H.21 Blood Volume and Cardiovascular Dysfunction

H.21.1 Hypovolemia and RAAS Dysfunction

Chronic hypovolemia (reduced blood volume) is a well-documented feature of ME/CFS, with direct consequences for oxygen delivery, exercise capacity, and orthostatic symptoms. Paradoxically, the renin-angiotensin-aldosterone system (RAAS) and antidiuretic hormone (ADH) — which normally activate in response to low blood volume — show suppression in ME/CFS patients.

Miwa & Fujita 2017 [837]: This study identified paradoxical down-regulation of volume-regulatory hormones in ME/CFS. Despite documented hypovolemia and reduced cardiac output, plasma aldosterone was 33% lower (104 ± 37 vs 157 ± 67 pg/ml, $p=0.004$) and ADH was 33% lower (2.2 ± 1.0 vs 3.3 ± 1.5 pg/ml, $p=0.02$) compared to healthy controls ($n=14$ patients, $n=13$ controls). Treatment trial: desmopressin (ADH analog) improved orthostatic symptoms in 50% of patients. **Certainty:** Medium (peer-reviewed, significant findings, but small sample awaiting replication). **Implication:** Hypovolemia results from central dysregulation of volume-regulatory systems, not excessive fluid loss.

Raj et al. 2005 [456]: Landmark study demonstrating the “renin-aldosterone paradox” in postural tachycardia syndrome (POTS), a condition overlapping with ME/CFS. Blood volume was markedly reduced (3583 ± 579 vs 4319 ± 578 mL, $p<0.0001$), with plasma volume 21% lower (2172 ± 429 vs 2763 ± 437 mL, $p<0.0001$). Despite this, plasma renin activity was unchanged and aldosterone was frankly low (7.0 ± 5.3 vs 12.3 ± 6.4 ng/dL, $p=0.01$). Strong positive correlation between blood volume and aldosterone ($r=0.56$, $p=0.001$). $n=33$ POTS patients, $n=13$ controls. **Certainty:** High (large sample, replicated, published in *Circulation*).

Mustafa et al. 2011 [838]: Identified abnormalities in angiotensin II regulation in POTS. Plasma Ang II was significantly elevated (43 ± 3 vs 28 ± 3 pg/mL, $p=0.006$), while estimated ACE2 activity was reduced (0.25 ± 0.02 vs 0.33 ± 0.03 , $p=0.038$). Elevated Ang II may contribute to peripheral vasoconstriction and reduced NO bioavailability. **Certainty:** Medium-High (peer-reviewed, mechanistic insight into RAAS dysfunction).

Stewart et al. 2006 [463]: Increased plasma angiotensin II in low-flow POTS patients related to reduced blood flow and blood volume. Suggests Ang II elevation is compensatory attempt to maintain blood pressure despite hypovolemia, but may contribute to local blood flow dysregulation. **Certainty:** Medium (mechanistic study linking Ang II to blood volume deficit).

Farquhar et al. 2002 [839]: Early study demonstrating relationship between blood volume and exercise capacity in CFS. Patients had significantly lower peak VO_2 consumption with trend toward lower blood volume. Strong correlation between blood volume and peak oxygen consumption, suggesting hypovolemia as physiological contributor to exercise intolerance. **Certainty:** Medium (established blood volume-exercise link).

van Campen et al. 2018 [470]: Dual-isotope blood volume measurement in ME/CFS adults. Mean absolute blood volume was 59(8) ml/kg, representing -11(7) ml/kg deficit below reference values. Blood volume reduction correlated with presence of orthostatic intolerance symptoms ($n=20$). **Certainty:** High (precise measurement technique, clear clinical correlation).

H.21.2 Cardiac Dysfunction and Natriuretic Peptides

Newton et al. 2016 [454]: CFS patients had significantly reduced cardiac volumes (both end-systolic and end-diastolic) with reduced end-diastolic wall masses. Strong positive correlations between total blood volume, red cell volume, plasma volume and cardiac end-diastolic wall mass. Critically, no relationship between disease length and cardiac/plasma volumes, ruling out deconditioning as sole cause. **Certainty:** High (cardiac MRI, objective measures, $n=42$ CFS patients). **Implication:** Reduced cardiac volumes are primary feature, not secondary to inactivity.

Tomas et al. 2017 [421]: Brain natriuretic peptide (BNP) levels significantly elevated in CFS cohort ($p=0.013$). Patients with high BNP (>400 pg/mL) had significantly lower cardiac volumes in both end-systolic and end-diastolic measurements ($p=0.05$). BNP elevation associated with cardiac dysfunction, not just volume overload. **Certainty:** Medium-High (established biomarker, cardiac imaging correlation).

H.21.3 Endothelial Dysfunction and Vascular Pathology

Scherbakov et al. 2020 [303]: Peripheral endothelial dysfunction found in 51% of ME/CFS patients vs 20% of healthy controls ($p<0.05$). Endothelial dysfunction assessed via flow-mediated dilation. Associated with disease severity and severity of immune symptoms ($n=35$ patients). **Certainty:** High (objective vascular measurement, peer-reviewed, ESC Heart Failure). **Implication:** Vascular pathology contributes to reduced blood flow and tissue perfusion.

Appel et al. 2024 [458]: Comprehensive review of endothelial dysfunction in ME/CFS. Elevated adhesion molecules (ICAM-1, VCAM-1), impaired flow-mediated dilation, chronic inflammatory state contributing to vascular pathology. Links endothelial dysfunction to exercise intolerance and post-exertional symptoms. **Certainty:** High (systematic review, multiple lines of evidence).

Miller et al. 2020 [464]: Arterial elasticity significantly increased in Ehlers-Danlos syndrome patients. Central pulse wave velocity significantly lower in EDS (4.73 m/s vs controls), indicating increased arterial elasticity that impairs baroreceptor-mediated blood pressure control. Explains orthostatic intolerance mechanism in EDS and related hypermobility conditions. $n=46$ EDS patients across multiple subtypes (primarily hEDS). **Certainty:** High (objective arterial measurements, published in *Genes*, significant finding). **Relevance to ME/CFS:** High comorbidity between ME/CFS and hEDS/hypermobility spectrum disorders. Increased arterial compliance reduces effectiveness of baroreceptor responses, contributing to orthostatic intolerance and POTS. Provides vascular mechanism linking connective tissue disorders to autonomic symptoms common in ME/CFS population.

H.21.4 Erythropoiesis and Red Blood Cell Function

Streeten DHP, Bell DS. 1998 [405]: Landmark early study measuring circulating blood volume in CFS patients using radiolabeled RBC and plasma volume techniques. Found: red blood cell mass reduced in 93.8% of female and 50% of male ME/CFS patients; plasma volume subnormal in 52.6%. Documented that blood volume deficits were consistent and substantial, with clear correlation to orthostatic intolerance symptoms. Provided first objective evidence that hypovolemia (not just deconditioning) contributes to exercise intolerance and symptom severity in ME/CFS. **Certainty:** High (gold-standard blood volume measurement technique, clear patient selection, objective methodology). **Clinical Implication:** Hypovolemia is a primary physiological feature of ME/CFS, not secondary consequence.

Saha et al. 2019 [306]: Red blood cell deformability significantly reduced in CFS patients using microfluidic measurements. Impaired RBC deformability can impair oxygen delivery to tissues and contribute to exercise intolerance and fatigue. $n=20$ CFS, $n=20$ controls. **Certainty:** Medium-High (novel methodology, replicated findings, published in clinical journal). **Implication:** Even with adequate RBC count, oxygen delivery may be compromised.

Winkler et al. 2004 [840]: Evaluation of serum erythropoietin levels and autonomic function in CFS. Examined potential relationships with anemia and fatigue severity. **Certainty:** Medium (exploratory study).

Świątczak et al. 2022 [841]: CFS patients show deteriorated iron metabolism: low serum iron, elevated ferritin, reduced transferrin saturation — pattern consistent with inflammatory anemia. Not true iron deficiency but iron sequestration due to inflammation. **Certainty:** Medium-High (clear pattern, n=multiple cohorts). **Link to cytokines:** IL-6 and hepcidin drive iron restriction.

Morceau et al. 2009 [842]: Mechanistic review: pro-inflammatory cytokines (IL-1, IL-6, TNF- α , IFN- γ) suppress erythropoiesis via multiple pathways including hepcidin induction, direct EPO suppression, and shortened RBC lifespan. **Relevance to ME/CFS:** Elevated cytokines documented in ME/CFS may contribute to functional anemia.

McCranor et al. 2014 [843]: IL-6 directly impairs erythroid differentiation in vitro, providing mechanistic link between cytokine elevation and anemia of chronic disease. **Certainty:** High (mechanistic study, controlled conditions).

Fraenkel 2017 [844]: Comprehensive review of anemia of inflammation: cytokine-mediated suppression of erythropoiesis, hepcidin-induced iron restriction, shortened RBC survival. **Application to ME/CFS:** Framework for understanding functional anemia despite normal hemoglobin in some patients.

H.21.5 Integrated Mechanisms: The Hypovolemia Cascade

The blood volume deficit in ME/CFS results from convergent mechanisms:

1. **RAAS/ADH suppression:** Paradoxical down-regulation prevents compensatory volume retention (Miwa 2017, Raj 2005)
2. **Plasma volume reduction:** Primary deficit in fluid compartment (Raj 2005: 21% reduction; van Campen 2018: -11 ml/kg)
3. **Cardiac consequences:** Reduced preload → reduced cardiac output → exercise intolerance (Newton 2016)
4. **Endothelial dysfunction:** Impaired vascular regulation → tissue hypoperfusion (Scherbakov 2020)
5. **RBC dysfunction:** Reduced deformability + inflammatory anemia → impaired oxygen delivery (Saha 2019, Świątczak 2022)
6. **Cytokine-mediated effects:** IL-6 and other cytokines suppress erythropoiesis and sequester iron (Morceau 2009, McCranor 2014)

This multi-hit model explains why simple volume expansion (saline infusion) provides only temporary benefit: underlying regulatory systems remain dysfunctional.

Clinical Implications:

- **Diagnostics:** Dual-isotope blood volume measurement may identify hypovolemic subgroup
- **Treatment targets:** Desmopressin for ADH-deficient patients (Miwa 2017); fludrocortisone for aldosterone supplementation; management of endothelial dysfunction; optimization of iron availability despite inflammation
- **Subtype identification:** Not all ME/CFS patients show same degree of hypovolemia; responders to volume-expanding interventions may represent distinct subgroup

Research Gaps:

- Mechanism of RAAS/ADH suppression (central dysregulation? autoimmune?)
- Predictors of desmopressin response
- Longitudinal blood volume changes over disease course
- Relationship between blood volume deficit and PEM severity
- Role of capillary permeability in plasma volume loss

H.23 Neuroimaging and Structural Brain Findings

H.23.1 Shan et al. 2020 — Neuroimaging Systematic Review (JTM)

Full Citation: Shan ZY, Barnden LR, Kwiatek RA, Bhuta S, Hermens DF, Lagopoulos J. Neuroimaging characteristics of myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS): a systematic review. *Journal of Translational Medicine*. 2020;18(1):335.

DOI: [10.1186/s12967-020-02506-6](https://doi.org/10.1186/s12967-020-02506-6)

PMID: 32887623

Study Design: Systematic review of structural and functional neuroimaging studies in ME/CFS

Key Findings:

- Inconsistent but recurring structural brain abnormalities across cohorts
- Prefrontal myelination upregulation reported in some studies
- Basal ganglia metabolite differences (elevated choline) and functional changes
- Insula gray matter volume increases in some studies
- Widespread functional connectivity disruptions across networks

Limitations: High heterogeneity across studies; inconsistent findings prevent definitive regional conclusions.

H.23.2 Finkelmeyer et al. 2017 — VBM Gray and White Matter in CFS

Full Citation: Finkelmeyer A, He J, MacLachlan L, Watson S, Gallagher P, Newton JL, Blamire AM. Grey and white matter differences in Chronic Fatigue Syndrome — A voxel-based morphometry study. *NeuroImage: Clinical*. 2017;17:24–30.

DOI: [10.1016/j.nicl.2017.09.024](https://doi.org/10.1016/j.nicl.2017.09.024)

PMID: 29021956

Sample Size: 42 CFS patients, 30 healthy controls; 3T MRI

Key Findings:

- Increased gray matter volume in the amygdala and insula (not reductions as initially hypothesized)
- Reduced white matter volume in midbrain, pons, and right temporal lobe
- Insula changes consistent with altered interoceptive processing
- Brainstem white matter reductions suggest pathway disruption

Note: Direction of regional changes contrasts with some earlier studies; illustrates the heterogeneity of neuroimaging findings in ME/CFS.

H.23.3 Puri et al. 2012 — VBM Regional Gray/White Matter Changes

Full Citation: Puri BK, Jakeman PM, Agour M, et al. Regional grey and white matter volumetric changes in myalgic encephalomyelitis (chronic fatigue syndrome): a voxel-based morphometry 3 T MRI study. *British Journal of Radiology*. 2012;85(1015):e270–e273.

DOI: [10.1259/bjr/93889091](https://doi.org/10.1259/bjr/93889091)

PMID: 22128128

Key Findings:

- Reduced gray matter volume in bilateral occipital poles, lateral occipital cortex, right angular gyrus, and posterior parahippocampal gyrus
- White matter reductions in the left occipital lobe
- Parahippocampal changes consistent with the memory impairment characteristic of ME/CFS

H.23.4 de Lange et al. 2004 — fMRI Neural Correlates of CFS

Full Citation: de Lange FP, Kalkman JS, Bleijenberg G, Hagoort P, van der Werf SP, van der Meer JWM, Toni I. Neural correlates of the chronic fatigue syndrome—an fMRI study. *Brain*. 2004;127(9):1948–1957.

DOI: [10.1093/brain/awh225](https://doi.org/10.1093/brain/awh225)

PMID: 15240435

Sample Size: 16 CFS patients, 16 healthy controls

Key Findings:

- CFS patients recruited additional or atypical brain regions during motor imagery tasks
- Stronger responses in visually related structures during motor tasks
- Error-related brain activity differed between groups, suggesting motor planning dysfunction
- Pattern consistent with compensatory over-recruitment and inefficient neural processing

H.24 Neurotransmitter and Neurochemical Findings

H.24.1 Yamamoto et al. 2004 — Serotonin Transporter Reduction in CFS

Full Citation: Yamamoto S, Ouchi Y, Onoe H, et al. Reduction of serotonin transporters of patients with chronic fatigue syndrome. *NeuroReport*. 2004;15(17):2571–2574.

DOI: [10.1097/00001756-200412030-00002](https://doi.org/10.1097/00001756-200412030-00002)

PMID: 15570154

Key Findings:

- PET imaging (DASB ligand) showed significantly reduced serotonin transporter density in CFS
- Reduction was most pronounced in the rostral subdivision of the anterior cingulate cortex (ACC)
- Demonstrates in vivo serotonergic dysfunction in ME/CFS using direct neuroimaging
- Provides neurobiological basis for sleep, mood, and cognitive symptoms in ME/CFS

H.24.2 Miller et al. 2014 — Basal Ganglia Activation and Dopamine in CFS

Full Citation: Miller AH, Jones JF, Drake DF, Tian H, Unger ER, Pagnoni G. Decreased Basal Ganglia Activation in Subjects with Chronic Fatigue Syndrome: Association with

Symptoms of Fatigue. *PLoS One*. 2014;9(5):e98156.

DOI: [10.1371/journal.pone.0098156](https://doi.org/10.1371/journal.pone.0098156)

PMID: 24858857

Sample Size: 18 CFS patients, 41 healthy controls

Key Findings:

- Significantly reduced right caudate nucleus and globus pallidus activation during reward tasks
- Diminished globus pallidus responsivity correlated with mental fatigue ($r^2 = 0.49$, $p = 0.001$)
- Proposes inflammatory cytokine-mediated disruption of basal ganglia dopamine availability
- Supports dopaminergic dysfunction as a contributor to ME/CFS fatigue

H.24.3 Dehghani et al. 2022 — Kynurenine Pathway and NAD⁺ in ME/CFS

Full Citation: Dehghani M, Panahi HKS, Kavyani B, et al. The Role of Kynurenine Pathway and NAD⁺ Metabolism in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Aging and Disease*. 2022;13(3):698–711.

DOI: [10.14336/AD.2021.0824](https://doi.org/10.14336/AD.2021.0824)

PMID: 35656104

Key Findings:

- Under inflammatory/IDO-1 activation, up to 90% of tryptophan is catabolized through the kynurenine pathway
- Pro-inflammatory cytokines (IFN- γ , TNF- α) documented in ME/CFS drive IDO-1 activity
- Kynurenine pathway overactivation depletes NAD⁺ and produces neurotoxic quinolinic acid accumulation
- Mechanistic explanation for reduced serotonin precursor availability and neurotransmitter imbalances in ME/CFS

H.25 Prognosis and Outcomes

H.25.1 Joyce, Hotopf and Wessely 1997 — Prognosis of CFS: Systematic Review

Full Citation: Joyce J, Hotopf M, Wessely S. The prognosis of chronic fatigue and chronic fatigue syndrome: a systematic review. *QJM: An International Journal of Medicine*. 1997;90(3):223–233.

DOI: [10.1093/qjmed/90.3.223](https://doi.org/10.1093/qjmed/90.3.223)

PMID: 9093600

Key Findings:

- **Pediatric:** 54–94% of children made good or complete recovery at 13–72 months (4 studies, $n = 15$ –31)
- **Adults:** Recovery rates substantially lower; improvement common but full recovery rare

- Recovery definition heterogeneity limits cross-study comparison
- Dramatically better pediatric outcomes support early and aggressive intervention

Significance: The 54–94% pediatric recovery range from this 1997 review remains the most cited figure in guidelines on pediatric ME/CFS prognosis.

H.25.2 Cairns and Hotopf 2005 — Adult CFS Prognosis: Systematic Review

Full Citation: Cairns R, Hotopf M. A systematic review describing the prognosis of chronic fatigue syndrome. *Occupational Medicine*. 2005;55(1):20–31.

DOI: [10.1093/occmed/kqi013](https://doi.org/10.1093/occmed/kqi013)

PMID: 15699087

Study Design: Systematic review of 14 studies meeting operational CFS criteria

Key Findings:

- Median full recovery rate: 5% (range 0–31%)
- Median proportion improving during follow-up: 39.5% (range 8–63%)
- Full recovery is rare in adult ME/CFS; sustained improvement without full recovery is more common
- Prognostic factors: illness beliefs, coping style, psychiatric comorbidity

Significance: Demonstrates the striking contrast with pediatric outcomes (54–94% recovery vs. 5% median in adults), supporting the urgency of early treatment in newly diagnosed patients.

H.26 Orthostatic Intolerance

H.26.1 Schondorf and Freeman 1999 — Importance of OI in CFS

Full Citation: Schondorf R, Freeman R. The importance of orthostatic intolerance in the chronic fatigue syndrome. *American Journal of Medical Sciences*. 1999;317(2):117–123.

DOI: [10.1097/00000441-199902000-00006](https://doi.org/10.1097/00000441-199902000-00006)

PMID: 10037115

Key Findings:

- Established orthostatic intolerance as a frequent and clinically important feature of CFS
- Demonstrates treatable autonomic dysfunction underlying many CFS symptoms
- Prevalence estimates across studies range from 50–97% depending on testing method and population
- Supports universal OI screening as a standard component of ME/CFS clinical evaluation

H.27 Treatment Evidence

H.27.1 Li et al. 2022 — tDCS of DLPFC for Neuropsychiatric Disorders

Full Citation: Li Q, Fu Y, Liu C, Meng Z. Transcranial Direct Current Stimulation of the Dorsolateral Prefrontal Cortex for Treatment of Neuropsychiatric Disorders. *Frontiers in Behavioral Neuroscience*. 2022;16:893955.

DOI: [10.3389/fnbeh.2022.893955](https://doi.org/10.3389/fnbeh.2022.893955)

Key Findings: • DLPFC is central to attention, decision-making, working memory, and executive function

- Anodal tDCS over left DLPFC improves working memory and attentional control in multiple studies
- Mechanism: modulates neuronal excitability of primary executive control regions
- Provides rationale for tDCS as a cognitive enhancement strategy in conditions of executive dysfunction

Note: Evidence base is primarily from depression and healthy volunteer studies; direct ME/CFS tDCS trials are limited.

H.27.2 Neuromodulation: Transcranial Magnetic Stimulation for ME/CFS

Samii et al. 1996 — Decreased Post-Exercise MEP Facilitation in CFS

Full Citation: Samii A, Wassermann EM, Ikoma K, Mercuri B, George MS, O'Fallon A, Dale JK, Straus SE, Hallett M. Decreased postexercise facilitation of motor evoked potentials in patients with chronic fatigue syndrome or depression. *Neurology*. 1996;47(6):1410–1414.

DOI: [10.1212/WNL.47.6.1410](https://doi.org/10.1212/WNL.47.6.1410)

PMID: 8960719

Study Design: Controlled diagnostic study using TMS as a neurophysiological probe (not therapy)

Sample Size: CFS patients vs. healthy controls (exact n not available from abstract)

Key Findings: After exercise, healthy controls showed motor evoked potential (MEP) amplitudes at 218% of baseline; CFS patients reached only 126%. This near-absence of post-exercise facilitation demonstrates objectively impaired motor cortex modulation in CFS, independent of effort or motivation.

Relevance: Foundational study establishing that ME/CFS involves measurable motor cortex dysfunction. Provides the neurophysiological rationale for therapeutic rTMS: if the motor cortex is hypoexcitable and fails to modulate normally, exogenous stimulation may restore function. Critically, this is an objective neurological finding, not a subjective symptom report.

Starr et al. 2000 — Motor Cortex Excitability in CFS

Full Citation: Starr A, Scalise A, Gordon R, Michalewski HJ, Caramia MD. Motor cortex excitability in chronic fatigue syndrome. *Clinical Neurophysiology*. 2000;111(11):2025–2031.

DOI: [10.1016/S1388-2457\(00\)00403-3](https://doi.org/10.1016/S1388-2457(00)00403-3)

PMID: 11068238

Study Design: Controlled neurophysiology study

Key Findings: CFS patients had significantly higher resting motor thresholds (reduced cortical excitability) and absent post-exercise MEP facilitation, confirming and extending Samii et al. 1996. The motor cortex in CFS requires stronger stimulation to produce a response and fails to upregulate after physical exertion.

Relevance: Independent replication of motor cortex hypoexcitability in CFS. Together with Samii 1996 and Davey 2003, establishes a consistent neurophysiological phenotype that rTMS could theoretically correct.

Miwa & Inoue 2023 — Dual-Target rTMS Ameliorates ME Symptoms

Full Citation: Miwa K, Inoue Y. Repetitive transcranial magnetic stimulation ameliorates symptoms in patients with myalgic encephalomyelitis (chronic fatigue syndrome). *IBRO Neuroscience Reports*. 2023;15:335–341.

DOI: [10.1016/j.ibneur.2023.11.002](https://doi.org/10.1016/j.ibneur.2023.11.002)

PMID: 38025661

Study Design: Open-label, single-arm (no sham control), $n = 30$

Population: ME patients (7 men, 23 women), mean age 39 ± 12 years, enrolled May 2015–March 2021

Protocol: Intermittent theta burst stimulation (iTBS): 3-pulse bursts at 50 Hz, repeated at 5 Hz, 600 pulses per site. Dual targets: left DLPFC (MRI-guided) and left M1 (motor hot spot). 10 sessions over 2-week inpatient stay. Intensity: 80% resting motor threshold (range 32–80% after tolerability adjustment).

Key Findings:

- Performance status: 67% achieved ≥ 2 -point improvement; median decreased from 7 to 5 ($p < 0.01$)
- Orthostatic intolerance: 83% (10/12) who could not complete standing test at baseline completed it post-treatment ($p < 0.01$)
- Disequilibrium: 88% (15/17) resolved; prevalence dropped from 57% to 7% ($p < 0.01$)
- Pain: 70% (7/10) showed ≥ 4 tender point reduction; median tender points $2 \rightarrow 0$ ($p < 0.01$)
- No serious adverse effects; 7 patients required intensity reduction for discomfort/-headache/dizziness

Relevance: Largest ME/CFS-specific rTMS study to date. The dual-target approach (DLPFC + M1) and particularly strong effects on orthostatic intolerance and disequilibrium distinguish this from depression-focused TMS protocols. However, the complete absence of sham control is a critical limitation—TMS produces strong expectancy effects, and the inpatient setting (rest, clinical attention) is itself therapeutic.

Certainty Assessment: TMS for ME/CFS (Aggregate)

- **Quality:** Low (all open-label, no sham controls, no blinding)
- **Sample:** ~72 patients total across all ME/CFS therapeutic studies
- **Replication:** Partial (two related Japanese groups; no independent replication outside Japan)
- **Mechanistic support:** Moderate (diagnostic TMS studies independently confirm motor cortex hypoexcitability)
- **Indirect support:** Moderate-to-strong (fibromyalgia sham-controlled meta-analyses show effects survive placebo for pain and quality of life: SMD -0.35 to -0.70 [25, 26])
- **Guideline status:** Not recommended by NICE for ME/CFS; Level B (probable efficacy) for fibromyalgia [24]
- **Overall certainty:** 0.30 — mechanistic rationale sound, but no controlled ME/CFS evidence exists
- **Clinical recommendation:** Investigational only; requires sham-controlled RCT before clinical adoption

H.27.3 Lang-Illievich et al. 2023 — PEA for Chronic Pain: Systematic Review and Meta-Analysis

Full Citation: Lang-Illievich K, Klivinyi C, Lasser C, et al. Palmitoylethanolamide in the Treatment of Chronic Pain: A Systematic Review and Meta-Analysis of Double-Blind Randomized Controlled Trials. *Nutrients*. 2023;15(6):1350.

DOI: [10.3390/nu15061350](https://doi.org/10.3390/nu15061350)

PMID: 36986081

Study Design: Systematic review and meta-analysis of 13 double-blind RCTs

Key Findings:

- Pooled effect favors PEA with mean pain reduction of 1.68 points on 11-point scale
- Pain reductions documented at 6 weeks, 8 weeks, and 24–26 weeks, supporting extended treatment
- Safety profile excellent; minimal side effects across all trials
- Superiority of micronized vs. standard PEA on clinical outcomes unclear; enhanced solubility may affect absorption

Significance: Provides the strongest meta-analytic evidence for PEA in chronic pain, supporting its use in ME/CFS patients with a pain component.

H.28 Coagulation and Vascular Pathology

H.28.1 Nunes et al. 2022 — Hyperactivated Platelets and Fibrinoid Microclots in ME/CFS

Full Citation: Nunes JM, Kruger A, Proal A, Kell DB, Pretorius E. The Occurrence of Hyperactivated Platelets and Fibrinoid Microclots in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). *Pharmaceuticals (Basel)*. 2022;15(8):931.

DOI: [10.3390/ph15080931](https://doi.org/10.3390/ph15080931)

PMID: 36015078

Study Design: Case-control study; ME/CFS patients vs. healthy controls; thromboelastography + fluorescent platelet microscopy

Key Findings:

- Fibrinoid microclot burden >10-fold greater in ME/CFS plasma than healthy controls
- ~80% of ME/CFS participants showed platelet hyperactivation (mean spreading score 2.72 vs. 1.00)
- Thromboelastography revealed hypercoagulable state in ~50% of participants
- Amyloid-resistant microclots may occlude microcapillaries, impairing tissue perfusion

Significance: First direct demonstration of ME/CFS-specific coagulation pathology paralleling Long COVID findings; opens potential therapeutic avenue via anticoagulation.

H.28.2 Suárez et al. 2010 — Nitric Oxide Metabolites During Exercise in CFS

Full Citation: Suárez A, Guillamó E, Roig T, et al. Nitric oxide metabolite production during exercise in chronic fatigue syndrome: a case-control study. *Journal of Women's Health*. 2010;19(6):1073–1077.

DOI: [10.1089/jwh.2008.1255](https://doi.org/10.1089/jwh.2008.1255)

PMID: 20469961

Study Design: Case-control; 44 female CFS patients vs. 25 healthy controls; maximal exercise testing

Key Findings:

- Plasma nitrate concentrations significantly higher in CFS patients during exercise
- Maximum difference ~295% above controls at maximal intensity
- Elevated NO metabolite response may indicate abnormal vascular regulation, not simple deficiency
- Authors suggest exercise-induced NO measurement as potential CFS biomarker

Significance: Demonstrates abnormal NO metabolism during exertion; challenges simple “endothelial NO deficiency” narrative; consistent with dysregulated vasoregulation rather than reduced production.

H.29 Lifestyle Intervention Safety

H.29.1 Kindlon 2011 — Reporting of Harms from GET and CBT in ME/CFS

Full Citation: Kindlon T. Reporting of harms associated with graded exercise therapy and cognitive behavioural therapy in myalgic encephalomyelitis/chronic fatigue syndrome. *Bulletin of the IACFS/ME*. 2011;19(2):59–111.

Key Findings:

- Systematic review of 10 patient surveys from four countries
- 51% of respondents reported GET worsened their health
- 20% reported similar worsening from CBT
- Critical methodological failures in RCTs: adverse events rarely tracked, patient compliance issues, subjective outcome bias

Significance: Foundational document establishing the evidence base for GET's harm profile in ME/CFS; directly influenced subsequent NICE guideline revision in 2021 removing GET as a recommended intervention.

H.30 Adenosine, Sleep Pressure, and Neuroinflammation

H.30.1 Huang et al. 2024 — Adenosine Receptors in Sleep Regulation

Full Citation: Huang L, Zhu W, Li N, Zhang B, Dai W, Li S, Xu H. Functions and mechanisms of adenosine and its receptors in sleep regulation. *Sleep Medicine*. 2024;115:210–217. DOI: 10.1016/j.sleep.2024.02.012.

Key Findings:

- Adenosine promotes sleep by inhibiting arousal systems and activating sleep-promoting systems via A1 and A2A receptor subtypes
- Astrocyte-derived adenosine is the primary source of homeostatic sleep pressure signal
- Caffeine's wake-promoting effect is mediated entirely through adenosine receptor blockade
- A1 receptors inhibit wake-active neurons; A2A receptors in the nucleus accumbens core drive sleep pressure

Relevance: Establishes the mechanistic framework for adenosine as homeostatic sleep signal. Forms the foundational reference for Section 15.3 (*Adenosine Accumulation and Pathological Sleep Pressure*).

Certainty Assessment:

- **Quality:** High (peer-reviewed review, Sleep Medicine)
- **Study type:** Narrative/mechanistic review
- **ME/CFS specificity:** None — establishes normal physiology
- **Limitation:** No primary data; no ME/CFS cohort

H.30.2 Retéy et al. 2007 — ADORA2A Genotype and Caffeine Sensitivity

Full Citation: Rétey JV, Adam M, Khatami R, Luhmann UFO, Jung HH, Berger W, Landolt HP. A genetic variation in the adenosine A2A receptor gene (ADORA2A) contributes to individual sensitivity to caffeine effects on sleep. *Clinical Pharmacology & Therapeutics*. 2007;81(5):692–698. DOI: 10.1038/sj.clpt.6100102.

Key Findings:

- ADORA2A c.1083T>C genotype distribution differs significantly between caffeine-sensitive and caffeine-insensitive adults
- Specific ADORA2A genotypes determine how closely caffeine-induced EEG changes resemble insomnia patterns
- Caffeine sensitivity is a functional readout of A2A receptor sensitivity at the individual level

Relevance: Provides the pharmacogenetic basis for understanding ME/CFS patients' variable caffeine responses as a potential marker of A2A receptor function. Supports the speculation that ME/CFS-associated A2A upregulation could alter caffeine pharmacodynamics.

Certainty Assessment:

- **Quality:** High (Clinical Pharmacology & Therapeutics, primary human study)
- **ME/CFS specificity:** None — general population caffeine-sleep study
- **Limitation:** No ME/CFS cohort; ME/CFS-specific caffeine-ADORA2A study remains unpublished

H.30.3 Orr et al. 2009 — A2A Receptor Mediates Microglial Process Retraction

Full Citation: Orr AG, Orr AL, Li X-J, Gross RE, Traynelis SF. Adenosine A2A receptor mediates microglial process retraction. *Nature Neuroscience*. 2009;12(7):872–878. DOI: 10.1038/nn.2341.

Key Findings:

- A2A adenosine receptors are upregulated on microglia coincident with P2Y12 downregulation during brain inflammation
- This receptor shift produces chemotactic reversal: activated microglia retract processes in response to adenosine (the ATP breakdown product) rather than extending toward it
- A2A signaling operates through Gs-adenylate cyclase-PKA pathway to drive amoeboid microglial morphology
- Human microglia show the same receptor expression pattern as mouse models

Relevance: Seminal mechanistic paper establishing the A2A upregulation-neuroinflammation link. Directly supports the hypothesis in Section 15.3 that ME/CFS neuroinflammation maintains elevated A2A receptor density in sleep-regulatory brain regions.

Certainty Assessment:

- **Quality:** High (Nature Neuroscience, top-tier journal)
- **Study type:** Primary mechanistic (mouse + human cell data)
- **ME/CFS specificity:** None — mechanism study
- **Limitation:** In vitro/animal model; extrapolation to ME/CFS requires supporting in vivo evidence

H.30.4 Navia et al. 2020 — Adenosine Receptors as Neuroinflammation Modulators

Full Citation: Navia M, et al. Adenosine Receptors as Neuroinflammation Modulators: Role of A1 Agonists and A2A Antagonists. *Cells*. 2020;9(7):1739. DOI: 10.3390/cells9071739.

Key Findings:

- A1 receptor agonism prevents cytokine (TNF- α , IL-1 β , IFN- γ) induced inflammation in mixed glial cells
- A2A receptor antagonism shows superior anti-inflammatory and antioxidant properties vs. A1 agonism
- A2A antagonist is effective in both in vitro glial models and in vivo neuroinflammation animal models
- Authors conclude A2A antagonism is a candidate strategy for chronic neuroinflammation therapy

Relevance: Provides mechanistic rationale for A2A receptor-targeted interventions in conditions with chronic glial activation, such as ME/CFS.

Certainty Assessment:

- **Quality:** Medium (Cells journal, in vitro + animal; no human trial)
- **ME/CFS specificity:** None
- **Limitation:** No clinical data; compounds tested not yet in ME/CFS trials

H.30.5 Chang et al. 2021 — Dysregulated Adenosine Homeostasis in Brain Disorders

Full Citation: Chang C-P, Wu K-C, Lin C-Y, Chern Y. Emerging roles of dysregulated adenosine homeostasis in brain disorders with a specific focus on neurodegenerative diseases. *Journal of Biomedical Science*. 2021;28(1):70. DOI: 10.1186/s12929-021-00766-y.

Key Findings:

- Adenosine homeostasis is regulated by ectonucleotidases (CD39, CD73), adenosine deaminase (ADA), and equilibrative nucleoside transporters (ENT1/ENT2)
- Dysregulation of any component leads to aberrant extracellular adenosine accumulation
- In neuroinflammatory and neurodegenerative conditions, impaired clearance through glial transporters is a consistent finding
- Adenosine functions as an endogenous anti-inflammatory agent; its dysregulation sustains microglial activation in a positive feedback loop

Relevance: Establishes the molecular machinery of adenosine clearance relevant to Section 15.3. ME/CFS reactive astrogliosis would be predicted to impair ENT1/ENT2-mediated clearance, raising basal adenosine.

Certainty Assessment:

- **Quality:** High (Journal of Biomedical Science, comprehensive review)
- **ME/CFS specificity:** None — focused on neurodegeneration
- **Limitation:** Mechanistic extrapolation to ME/CFS; no direct measurement of ENT expression in ME/CFS glia

H.30.6 Rábago-Monzón et al. 2025 — Astrocytes, Microglia, and Sleep Dysregulation

Full Citation: Rábago-Monzón ÁR, Osuna-Ramos JF, Armienta-Rojas DA, et al. Stress-Induced Sleep Dysregulation: The Roles of Astrocytes and Microglia in Neurodegenerative and Psychiatric Disorders. *Biomedicines*. 2025;13(5):1121. DOI: 10.3390/biomedicines13051121.

Key Findings:

- Astrocytes regulate sleep architecture via two primary mechanisms: adenosine signaling and glymphatic clearance
- Chronic stress disrupts both pathways, reducing restorative sleep quality
- Microglial neuroinflammation further degrades sleep quality through synaptic dysfunction
- Convergence of adenosine dysregulation and glymphatic failure on synaptic pruning and plasticity is documented

Relevance: Directly links the glial biology of ME/CFS (neuroinflammation, reactive astrogliosis) to the sleep complaints that are central to the disease. Supports the integration of Section 15.3 with Section 15.10 (glymphatic failure).

Certainty Assessment:

- **Quality:** Medium (Biomedicines, mechanistic synthesis review; 2025)
- **ME/CFS specificity:** None
- **Limitation:** Synthesis paper; primary data for ME/CFS application is indirect

H.30.7 Nakatomi et al. 2014 — TSPO-PET Neuroinflammation in ME/CFS

Full Citation: Nakatomi Y, Mizuno K, Ishii A, et al. Neuroinflammation in Patients with Chronic Fatigue Syndrome/Myalgic Encephalomyelitis: An ^{11}C -(R)-PK11195 PET Study. *Journal of Nuclear Medicine*. 2014;55(6):945–950. DOI: 10.2967/jnumed.113.131045.

Key Findings:

- TSPO binding (microglial activation marker) elevated 45–199% in ME/CFS patients vs. healthy controls
- Affected regions: cingulate cortex, hippocampus, amygdala, thalamus, midbrain, pons
- Regional neuroinflammation correlated with cognitive impairment, pain, and depression severity
- First direct in vivo neuroinflammation evidence in ME/CFS via PET imaging

Relevance: Landmark study providing the neuroinflammatory substrate that mechanistically supports A2A upregulation and adenosine dysregulation in ME/CFS. The affected brain regions overlap substantially with sleep-regulatory circuitry (cingulate, thalamus, brainstem).

Certainty Assessment:

- **Quality:** High (Journal of Nuclear Medicine; in vivo patient data)
- **Sample:** n=9 ME/CFS patients, n=10 healthy controls
- **Replication:** Partially replicated by subsequent PET and MRS studies (Younger group)

- **Limitation:** Small sample; single centre; TSPO binding is a marker of glial activation, not exclusive to microglia

H.30.8 Maksoud et al. 2021 — Systematic Review of Sleep in ME/CFS

Full Citation: Maksoud R, Eaton-Fitch N, Matula M, Cabanas H, Staines D, Marshall-Gradisnik S. Systematic Review of Sleep Characteristics in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Healthcare*. 2021;9(5):568. DOI: 10.3390/healthcare9050568.

Key Findings:

- Non-restorative sleep reported by approximately 91% of ME/CFS patients
- Increased microarousal index (MAI) is the single most consistent polysomnographic abnormality: elevated in all five studies that measured it
- Sleep onset latency is uniformly normal across 13 studies — sleep initiation is intact
- Major discrepancy between subjective sleep complaints and aggregate polysomnographic measures
- Pattern suggests pathology in sleep maintenance and quality, not in sleep initiation

Relevance: Provides the clinical sleep phenotype that the adenosine hypothesis in Section 15.3 must explain. The preserved sleep onset latency with elevated microarousal index is mechanistically consistent with adenosine-mediated sleep maintenance disruption rather than a simple sleep pressure deficit.

Certainty Assessment:

- **Quality:** High (systematic review, Healthcare)
- **Study type:** Systematic review of polysomnographic studies
- **Limitation:** Heterogeneous populations and methods across included studies; no biomarker data linking sleep findings to adenosine specifically

Section 15.6 — Melatonin Dysfunction and Circadian Disruption

McCarthy 2022 — Circadian Rhythm Disruption in ME/CFS and Long COVID

M. J. McCarthy. “Circadian rhythm disruption in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: Implications for the post-acute sequelae of COVID-19”. In: *Brain, Behavior, & Immunity – Health* 20 (2022). Narrative review linking circadian disruption to ME/CFS and long COVID pathophysiology. Key finding: ME/CFS patients lack the midday temperature increase seen in controls and show distinct evening temperature drop, indicating multi-system circadian decoupling. DLMO timing is dissociated from temperature rhythm (intact in controls, absent in ME/CFS). TGFβ dysregulation proposed as mechanistic driver of peripheral clock disruption. Melatonin effective only in phase-delayed subset., p. 100412. DOI: [10.1016/j.bbih.2022.100412](https://doi.org/10.1016/j.bbih.2022.100412)

Key Findings:

- ME/CFS patients lack the midday temperature increase seen in healthy controls and show a distinct evening temperature drop, indicating multi-system circadian decoupling beyond melatonin timing alone
- DLMO timing is dissociated from body temperature rhythm in ME/CFS (both rhythms correlate in controls; correlation absent in patients)

- TGFB (transforming growth factor beta) dysregulation proposed as mechanistic driver of peripheral clock disruption via SMAD protein signalling
- Melatonin treatment shows preferential benefit only in the phase-delayed subset of ME/CFS patients
- ME/CFS findings may illuminate long COVID (PASC) pathophysiology given shared circadian disruption

Relevance: Provides the mechanistic framework for Section 15.6, establishing that circadian disruption in ME/CFS is multi-system and not reducible to simple delayed DLMO. The TGFB link connects circadian dysfunction to the immune dysregulation documented elsewhere in the chapter.

Certainty Assessment:

- **Quality:** Medium (narrative review, single author, Brain Behav Immun Health)
- **Study type:** Narrative review
- **Limitation:** No new primary data; synthesises older studies with heterogeneous methods; TGFB mechanistic link is theoretical

van Heukelom et al. 2006 — Melatonin for CFS with Late DLMO

R. O. van Heukelom et al. "Influence of melatonin on fatigue severity in patients with chronic fatigue syndrome and late melatonin secretion". In: *European Journal of Neurology* 13.1 (2006). n=29 CFS patients with DLMO later than 21:30h. Open-label: 5mg melatonin orally 5h before DLMO for 3 months. CIS questionnaire: total score and sub-scores for fatigue, concentration, motivation, and activity improved significantly. Fatigue normalised in 8/27 vs. 2/29 pre-treatment (significant). Patients with DLMO later than 22:00h (n=21) showed greater benefit than earlier DLMO group (n=8). Supports DLMO-guided melatonin timing; no control group limits causal inference., pp. 55–60. doi: [10.1111/j.1468-1331.2006.01132.x](https://doi.org/10.1111/j.1468-1331.2006.01132.x)

Key Findings:

- 29 CFS patients with DLMO >21:30h treated with 5 mg melatonin orally 5 h before DLMO for 3 months
- CIS total score and sub-scores (fatigue, concentration, motivation, activity) all improved significantly post-treatment
- Fatigue normalised in 8/27 patients during treatment vs. 2/29 pre-treatment ($p < 0.05$)
- Patients with DLMO >22:00h ($n = 21$) showed significantly greater benefit than those with DLMO 21:30–22:00h ($n = 8$)
- Supports DLMO-guided timing as a clinically meaningful stratification variable

Relevance: Primary ME/CFS-specific evidence for melatonin treatment stratified by DLMO. Directly supports the therapeutic approach described in Section 15.6 and the rationale for DLMO assessment before prescribing melatonin.

Certainty Assessment:

- **Quality:** Medium (European Journal of Neurology, peer-reviewed)
- **Sample:** n=29
- **Replication:** Not replicated as a controlled trial

- **Limitation:** Open-label, no placebo control; significant pre-treatment improvement in fatigue sub-score complicates attribution

Knook et al. 2000 — High Nocturnal Melatonin in Adolescent ME/CFS

L. Knook et al. “High nocturnal melatonin in adolescents with chronic fatigue syndrome”. In: *Journal of Clinical Endocrinology & Metabolism* 85.10 (2000). n=13 adolescent CFS vs. n=15 healthy controls. Saliva melatonin hourly 17:00–02:00h. Nocturnal melatonin significantly elevated in CFS at midnight, 01:00h, and 02:00h ($p < 0.001$). Timing of melatonin rise did not differ. All CFS patients reported unrefreshing sleep vs. 1 control. Conclusion: melatonin supplementation not indicated in this subgroup given already elevated levels. Highlights heterogeneity: adult delayed vs. adolescent elevated-amplitude phenotypes., pp. 3690–3692. DOI: [10.1210/jcem.85.10.6857](https://doi.org/10.1210/jcem.85.10.6857)

Key Findings:

- 13 adolescent CFS patients showed significantly elevated nocturnal salivary melatonin at midnight, 01:00h, and 02:00h compared to 15 controls ($p < 0.001$)
- Timing of melatonin rise did not differ between groups — amplitude, not phase, was abnormal
- All CFS patients reported unrefreshing sleep vs. only 1 control, despite similar sleep-onset time and duration
- Authors concluded melatonin supplementation is not indicated in this subgroup

Relevance: Demonstrates phenotypic heterogeneity in ME/CFS melatonin abnormalities: elevated amplitude (adolescents) vs. delayed phase (adults). Critical for Section 15.6 to avoid overgeneralising treatment recommendations and to frame melatonin abnormalities as bidirectional.

Certainty Assessment:

- **Quality:** Medium (J Clin Endocrinol Metab, peer-reviewed)
- **Sample:** n=13 patients, n=15 controls
- **Replication:** Not replicated; small sample
- **Limitation:** Very small sample; adolescent-only; no adult comparison arm

Mohamed et al. 2023 — Objective Sleep Measures in ME/CFS: Meta-Analysis

A. Z. Mohamed et al. “Objective sleep measures in chronic fatigue syndrome patients: A systematic review and meta-analysis”. In: *Sleep Medicine Reviews* 69 (2023). Systematic review and meta-analysis: 24 case-control studies; 20 adult studies (ME/CFS n=426, controls n=375) and 4 adolescent studies (ME/CFS n=242, controls n=235). Adults: longer sleep onset latency, longer WASO, reduced sleep efficiency, decreased stage N2, more stage N3 (SWS), longer REM latency. Adolescents: longer TIB, longer TST, longer SOL, reduced efficiency. Results suggest autonomic (sympathetic/parasympathetic) alterations in ME/CFS. No conflicts of interest., p. 101771. DOI: [10.1016/j.smr.2023.101771](https://doi.org/10.1016/j.smr.2023.101771)

Key Findings:

- Largest meta-analysis of objective sleep measures in ME/CFS: 24 studies, 801 adults and 477 adolescents

- Adults: longer sleep onset latency, longer wake after sleep onset (WASO), reduced sleep efficiency, decreased stage N2, more stage N3 (slow-wave sleep), longer REM latency
- Adolescents: longer TIB, longer TST, longer SOL, reduced sleep efficiency
- Paradoxical increase in slow-wave sleep despite unrefreshing experience suggests quality impairment, not simply quantity reduction
- Findings suggest sympathetic/parasympathetic nervous system alterations contribute to sleep disruption

Relevance: Provides the sleep architecture phenotype that melatonin dysfunction must help explain. The preserved or increased SWS alongside unrefreshing sleep is mechanistically important: circadian misalignment may fragment the restorative quality of SWS without reducing its measured duration.

Certainty Assessment: • **Quality:** High (Sleep Medicine Reviews, systematic review and meta-analysis)

- **Sample:** 24 studies, 1278 total participants
- **Replication:** Meta-analytic synthesis across multiple independent cohorts
- **Limitation:** Heterogeneity across included studies; no direct melatonin measurement data; no conflicts of interest

Burgess et al. 2010 — Phase Response Curves: 0.5 mg vs 3.0 mg Melatonin

H. J. Burgess et al. "Human phase response curves to three days of daily melatonin: 0.5 mg versus 3.0 mg". In: *Journal of Clinical Endocrinology & Metabolism* 95.7 (2010). n=34 healthy adults (16M/18F, ages 18–42), double-blind placebo-controlled. Phase response curves for 0.5mg vs 3.0mg oral melatonin. Maximum circadian phase advances with 0.5mg occurred 2–4h before DLMO or 9–11h before sleep midpoint. When each dose given at its optimal time, both 0.5mg and 3.0mg produce similarly sized phase advances and delays. Optimal timing for advances is later for the lower dose. Supports low-dose (0.5mg) melatonin as effective chronobiotic without suppressing endogenous secretion., pp. 3325–3331. doi: [10.1210/jc.2009-2590](https://doi.org/10.1210/jc.2009-2590)

Key Findings: • Maximum circadian phase advances with 0.5 mg melatonin occurred 2–4 h before DLMO or 9–11 h before sleep midpoint

- When given at optimal timing, both 0.5 mg and 3.0 mg produce similarly sized phase advances and delays
- Optimal administration time for advances is later for the lower (0.5 mg) dose
- Low-dose melatonin avoids pharmacological sedation and supraphysiological blood levels that may suppress endogenous pineal secretion

Relevance: Provides the pharmacological rationale for low-dose melatonin (0.5 mg) as preferred therapeutic dosing in ME/CFS. Since endogenous melatonin function is already abnormal, avoiding suppression of residual secretion is clinically important. Directly supports the dosing recommendations in Section 15.6.

Certainty Assessment: • **Quality:** High (J Clin Endocrinol Metab, double-blind placebo-controlled trial in healthy adults)

- **Sample:** n=34 healthy adults
- **Replication:** Foundational PRC study; findings consistent with prior melatonin PRC literature
- **Limitation:** Healthy adults only; ME/CFS-specific PRC not characterised; extrapolation required

Swanson et al. 2024 — Low-Dose Melatonin + Dim Light for DSWPD

L. M. Swanson et al. “Low-dose exogenous melatonin plus evening dim light and time in bed scheduling advances circadian phase irrespective of measured or estimated dim light melatonin onset time: preliminary findings”. In: *Journal of Clinical Sleep Medicine* 20.7 (2024). RCT, n=40 adults with DSWPD, randomised to 0.5mg melatonin 3h before measured DLMO vs. 5h before estimated sleep onset (actigraphy), plus behavioural interventions (evening dim light, time-in-bed scheduling) for 4 weeks. Significant improvements in DLMO timing, sleep-onset/offset, Morningness-Eveningness score, fatigue (MFI), PROMIS sleep disturbance after Bonferroni correction. No group-by-visit interaction: DLMO estimation as effective as measurement. Preliminary; larger trial needed. Conflict: Burgess on advisory board Natrol LLC., pp. 1131–1140. DOI: [10.5664/jcsm.11076](https://doi.org/10.5664/jcsm.11076)

Key Findings:

- RCT (n = 40, DSWPD): 0.5 mg melatonin timed to measured or estimated DLMO, plus evening dim light and time-in-bed scheduling for 4 weeks
- Significant improvements in DLMO timing, sleep-onset and sleep-offset, Morningness-Eveningness score, fatigue (MFI), and PROMIS sleep disturbance/impairment (Bonferroni corrected)
- No significant difference between groups: DLMO estimation via actigraphy was as effective as formal DLMO measurement for scheduling melatonin
- Multimodal approach (melatonin + light hygiene + scheduling) appears synergistic

Relevance: Most clinically applicable RCT for the Section 15.6 treatment strategy. Supports multi-modal approach combining low-dose melatonin with circadian hygiene measures. The equivalence of estimated vs. measured DLMO has practical implications for clinical settings where formal DLMO testing is unavailable.

Certainty Assessment:

- **Quality:** High (J Clin Sleep Med, RCT)
- **Sample:** n=40
- **Replication:** Preliminary; authors state larger confirmatory trial needed
- **Limitation:** DSWPD patients, not ME/CFS; Burgess has industry advisory relationship (Natrol LLC)

Reiter et al. 2016 — Melatonin as Mitochondria-Targeted Antioxidant

R. J. Reiter et al. “Melatonin as an antioxidant: under promises but over delivers”. In: *Journal of Pineal Research* 61.3 (2016). Comprehensive review by Reiter group. Melatonin reduces oxidative stress via: direct scavenging of ROS and RNS, stimulation of antioxidant enzymes (SOD, GPx, catalase), suppression of pro-oxidant enzymes, chelation of transition metals

(reducing Fenton/Haber-Weiss hydroxyl radical production). Mitochondrial melatonin concentrations greatly exceed blood levels, positioning it as mitochondria-targeted antioxidant. Metabolites AFMK and AMK also antioxidant-active. Foundational reference for melatonin antioxidant role relevant to NO/ONOO cycle and oxidative stress sections., pp. 253–278. doi: [10.1111/jpi.12360](https://doi.org/10.1111/jpi.12360)

Key Findings:

- Melatonin concentrations in mitochondria greatly exceed blood levels, establishing it as a mitochondria-targeted antioxidant
- Mechanisms: direct ROS/RNS scavenging; stimulation of SOD, GPx, catalase; suppression of pro-oxidant enzymes; transition metal chelation
- Metabolites AFMK and AMK retain antioxidant activity, providing a “cascade” of protection
- Effective against ischaemia/reperfusion injury in brain and heart; combats drug toxicity and chemotherapy resistance

Relevance: Provides the biochemical basis for melatonin’s antioxidant role referenced in both Section 15.6 and Section 15.12 (Oxidative and Nitrosative Stress). In ME/CFS, where mitochondrial dysfunction and oxidative stress co-occur, melatonin deficiency or disruption may amplify ROS accumulation. Foundational reference for the antioxidant pathway.

Certainty Assessment:

- **Quality:** High (Journal of Pineal Research, comprehensive review by leading melatonin researchers)
- **Study type:** Narrative/mechanistic review
- **Limitation:** Predominantly animal and in vitro data; human RCT evidence for antioxidant effects in chronic disease is limited; no conflicts stated

Liang et al. 2024 — Melatonin Enhances NK Cell Function via JAK3-STAT5

C. Liang et al. “Melatonin enhances NK cell function in aged mice by increasing T-bet expression via the JAK3-STAT5 signaling pathway”. In: *Immunity & Ageing* 21.1 (2024). Mouse model (aged mice). Melatonin significantly increased NK cell number and function: proliferation, degranulation, and IFN- γ secretion. Mechanism: JAK3/STAT5 signalling leads to increased T-bet expression, driving NK cell maturation and activation. Relevant to ME/CFS context of NK cell hypofunctionality: melatonin deficit from circadian disruption may contribute to reduced NK cytotoxicity. Erratum published 2024 Oct (minor correction). No conflicts of interest., p. 59. doi: [10.1186/s12979-024-00459-8](https://doi.org/10.1186/s12979-024-00459-8)

Key Findings:

- Melatonin significantly increased NK cell number, proliferation, degranulation, and IFN- γ secretion in aged mice
- Mechanism: JAK3/STAT5 signalling pathway → increased T-bet expression → NK cell maturation and activation
- Provides molecular mechanism linking melatonin to NK cell function, relevant to ME/CFS NK hypofunctionality

Relevance: NK cell cytotoxicity is consistently reduced in ME/CFS. This paper provides a mechanistic explanation for how circadian disruption and melatonin deficiency could

contribute to NK dysfunction: loss of melatonin-driven JAK3/STAT5/T-bet signalling. Directly supports the melatonin-immune axis discussion in Section 15.6.

Certainty Assessment: • **Quality:** Medium (Immunity & Ageing, open access, peer-reviewed)

- **Sample:** Animal model (aged mice); no human data
- **Replication:** Single study; mechanistic pathway not yet confirmed in humans
- **Limitation:** Mouse model only; extrapolation to human ME/CFS is speculative; erratum published (minor correction)

Anderson & Maes 2020 — Mitochondria and Immunity in ME/CFS

G. Anderson and M. Maes. “Mitochondria and immunity in chronic fatigue syndrome”. In: *Progress in Neuropsychopharmacology and Biological Psychiatry* 103 (2020). Review. Proposes gut and immune cell mitochondria as two central hubs in ME/CFS pathophysiology, interacting with circadian rhythm and melatonin. Also implicates gut microbiome and permeability, endogenous opioidergic system, autonomic nervous system, microRNA-155, viral reactivation, and leptin. Positions melatonin/circadian disruption as upstream regulator of mitochondrial and immune dysfunction in ME/CFS, with therapeutic implications., p. 109976. doi: [10.1016/j.pnpbp.2020.109976](https://doi.org/10.1016/j.pnpbp.2020.109976)

Key Findings: • Proposes gut and immune cell mitochondria as two central hubs in ME/CFS pathophysiology

- Circadian rhythm and melatonin identified as upstream regulatory factors interacting with mitochondrial function
- Also implicates gut microbiome/permeability, endogenous opioidergic system, autonomic nervous system, microRNA-155, viral reactivation, and leptin
- Positions melatonin/circadian disruption as an upstream driver that compounds mitochondrial and immune dysfunction

Relevance: Provides the integrative framework connecting Section 15.6 (melatonin/circadian) to the bioenergetic and immune dysfunction chapters. Useful for establishing why melatonin interventions may have effects beyond sleep, reaching mitochondrial function and immune regulation.

Certainty Assessment: • **Quality:** Medium (Progress in Neuropsychopharmacology and Biological Psychiatry, review)

- **Study type:** Narrative review
- **Limitation:** Theoretical/mechanistic; most proposed interactions not yet tested experimentally in ME/CFS; authors (Anderson, Maes) have published extensively in this theoretical space — assess for confirmation bias

Section 15.7: Microglia Activation and Neuroinflammatory Fatigue

VanElzakker, Brumfield & Lara Mejia 2019 — Critical Review of Neuroinflammation Methods in ME/CFS

M. B. VanElzakker, S. A. Brumfield, and P. S. Lara Mejia. "Neuroinflammation and Cytokines in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS): A Critical Review of Research Methods". In: *Frontiers in Neurology* 9 (2019). Critical methodological review of neuroinflammation measurement in ME/CFS (PET, MRS, cytokine assays). Key argument: most neuroimaging studies inadequately target the brainstem despite its probable centrality to neuroinflammatory causes. Significant methodological inconsistencies undermine reliability of peripheral cytokine profiling. Essential reference for interpreting the heterogeneous neuroinflammation literature., p. 1033. DOI: [10.3389/fneur.2018.01033](https://doi.org/10.3389/fneur.2018.01033). URL: <https://pubmed.ncbi.nlm.nih.gov/30687207/>

Key Findings:

- Critical methodological review of PET, MRS, and cytokine assay approaches to measuring neuroinflammation in ME/CFS
- Most neuroimaging studies inadequately target the brainstem, which is proposed as probable primary site of neuroinflammatory activity
- Peripheral cytokine profiling unreliable for diagnosis due to measurement variability and biological complexity
- Positions TSPO-PET as the strongest available method but notes second-generation ligands needed to overcome binding potential issues of PK11195

Relevance: Essential methodological reference for interpreting the heterogeneous neuroinflammation literature. Contextualises why the Nakatomi 2014 and Raijmakers 2021 TSPO-PET studies reach contradictory conclusions. Argues that future studies must target brainstem specifically.

Certainty Assessment:

- **Quality:** High (Frontiers in Neurology; peer-reviewed methods review)
- **Study type:** Critical review — no new empirical data
- **Limitation:** Cannot resolve empirical contradictions in the primary literature; advocates for better methods rather than providing them

Renz-Polster, Tremblay, Bienzle & Fischer 2022 — Neuroglial Failure Hypothesis

H. Renz-Polster et al. "The Pathobiology of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: The Case for Neuroglial Failure". In: *Frontiers in Cellular Neuroscience* 16 (2022). Comprehensive hypothesis paper arguing that impaired or pathologically reactive neuroglia (astrocytes, microglia, oligodendrocytes) represent the common pathobiological denominator in ME/CFS. Proposes neuroglial dysfunction explains PEM, reduced cerebral blood flow, and cognitive symptoms. Mechanistic detail on microglial reactivity states (M1/M2-like), complement activation, synaptic pruning dysregulation, and relevance to Long COVID. High-quality theoretical synthesis., p. 888232. DOI: [10.3389/fncel.2022.888232](https://doi.org/10.3389/fncel.2022.888232). URL: <https://pubmed.ncbi.nlm.nih.gov/35614970/>

Key Findings:

- Proposes impaired or pathologically reactive neuroglia (astrocytes, microglia, oligodendrocytes) as the common pathobiological denominator in ME/CFS
- Reactive microglia shift to M1-like state, releasing $\text{TNF-}\alpha$, $\text{IL-1}\beta$, IL-6 , and reactive oxygen species, suppressing neural circuit efficiency
- Complement cascade (C1q, C3) may drive excess synaptic pruning by activated microglia, contributing to cognitive symptoms
- Neuroglial failure could explain post-exertional malaise: during activity, glial metabolic support to neurons fails under increased demand
- Directly applicable to Long COVID, which shows similar neuroglial activation on post-mortem analysis

Relevance: Provides the integrative mechanistic framework for Section 15.7. Connects microglia M1/M2 phenotypes, complement activation, synaptic pruning excess, and PEM into a single explanatory model. Co-authored by Marie-Eve Tremblay, a leading microglia researcher.

Certainty Assessment:

- **Quality:** High (Frontiers in Cellular Neuroscience; expert authorship)
- **Study type:** Hypothesis/narrative review — no original data
- **Limitation:** Theoretical synthesis; individual component mechanisms extrapolated from other diseases (Alzheimer's, MS, viral encephalitis); not yet tested as a unified hypothesis in ME/CFS specifically

Gottschalk, Peterson, Knox, Maynard & Whelan 2022 — ATG13 Drives Microglial Oxidative Stress via RAGE

C. G. Gottschalk et al. "Elevated ATG13 in serum of patients with ME/CFS stimulates oxidative stress response in microglial cells via activation of receptor for advanced glycation end products (RAGE)". in: *Molecular and Cellular Neuroscience* 120 (2022). Mechanistic study demonstrating ME/CFS patient serum stimulates reactive oxygen species (ROS) and nitric oxide production in human HMC3 microglial cells. ATG13 (autophagy-related protein 13), elevated in ME/CFS serum, activates RAGE receptors to trigger microglial oxidative stress; ATG13 neutralization substantially reduced this response. Provides direct ex vivo evidence for circulating factors driving microglial activation in ME/CFS., p. 103731. doi: [10.1016/j.mcn.2022.103731](https://doi.org/10.1016/j.mcn.2022.103731). URL: <https://pubmed.ncbi.nlm.nih.gov/35487443/>

Key Findings:

- ME/CFS patient serum directly stimulates reactive oxygen species (ROS) and nitric oxide production in human HMC3 microglial cells *in vitro*
- ATG13 (autophagy-related protein 13), elevated in ME/CFS serum, identified as the active factor via RAGE receptors on microglia
- ATG13 neutralisation substantially reduces the microglial oxidative stress response
- Provides a mechanistic link between impaired autophagy (a peripheral ME/CFS feature) and central microglial activation

Relevance: Supports the circulating-factors model of neuroinflammation: peripheral ME/CFS abnormalities can directly activate brain microglia. Provides a specific molecular mechanism (ATG13/RAGE axis) amenable to therapeutic targeting.

- Certainty Assessment:**
- **Quality:** Medium (Molecular and Cellular Neuroscience; peer-reviewed)
 - **Study type:** In vitro mechanistic study (HMC3 cell line)
 - **Sample:** Human serum from ME/CFS patients (sample size not reported in abstract)
 - **Limitation:** In vitro only; does not demonstrate the mechanism operates at equivalent magnitude in living patients; cell line model (HMC3) is not primary human microglia; single study needing replication

Miwa 2021 — Oral Minocycline Trial in Myalgic Encephalomyelitis

K. Miwa. “Oral Minocycline Therapy Improves Symptoms of Myalgic Encephalomyelitis, Especially in the Initial Disease Stage”. In: *Internal Medicine* 60.16 (2021). Open-label prospective study of oral minocycline (100 mg/day for 42 days) in 100 ME patients. Favorable response (performance status improvement ≥ 2 points) in 27 patients (27%); best response in patients within 6 months of disease onset. Rationale: minocycline attenuates microglial activation and exerts anti-inflammatory, neuroprotective effects. 38% discontinued due to adverse effects (nausea, dizziness). No control group. Low certainty due to design., pp. 2577–2584. DOI: [10.2169/internalmedicine.6082-20](https://doi.org/10.2169/internalmedicine.6082-20). URL: <https://pubmed.ncbi.nlm.nih.gov/33896862/>

- Key Findings:**
- Open-label prospective trial: oral minocycline 100 mg/day for 42 days in 100 ME patients
 - Favourable response (performance status improvement ≥ 2 points) in 27 patients (27%)
 - Best response in patients within 6 months of disease onset
 - Rationale: minocycline inhibits microglial activation and exerts anti-inflammatory, immunomodulatory, and neuroprotective effects
 - 38% discontinued due to adverse effects (nausea, dizziness, photosensitivity)

Relevance: Primary clinical evidence for minocycline as a microglial modulator in ME/CFS. Supports the hypothesis that neuroinflammation is most therapeutically accessible in early-stage disease. Directly relevant to Section 15.7 therapeutic strategies discussion.

- Certainty Assessment:**
- **Quality:** Low-Medium (Internal Medicine; open-label single-arm)
 - **Sample:** n=100
 - **Study type:** Open-label prospective; no control group; no blinding; Japanese single-centre
 - **Limitation:** No randomisation; significant dropout (38%); Japanese cohort may not generalise; response rate (27%) modest; performance status is a subjective endpoint
 - **Replication:** Partially replicated in Miwa 2024 pilot (PMID 39720104) with higher response rate in early-stage Long COVID-ME

Numata 2021 — Commentary: Minocycline as Microglial Modulator

T. Numata. "Could Minocycline Be a "Magic Bullet" for the Treatment of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome?" In: *Internal Medicine* 60.16 (2021). Editorial commentary on Miwa 2021 minocycline trial. Acknowledges minocycline's mechanism (microglial suppression, anti-inflammatory, neuroprotective) as theoretically sound for ME/CFS neuroinflammation. Argues against "magic bullet" framing due to disease heterogeneity. Advocates stratified patient classification by onset, duration, and confirmed pathology before testing targeted interventions., pp. 2527–2528. doi: [10.2169/internalmedicine.7182-21](https://doi.org/10.2169/internalmedicine.7182-21). URL: <https://pubmed.ncbi.nlm.nih.gov/33814504/>

Key Findings:

- Editorial affirming minocycline's mechanism (microglial suppression) as theoretically sound for ME/CFS neuroinflammation
- Argues against "magic bullet" framing: ME/CFS heterogeneity means no single agent will benefit all patients
- Advocates stratified patient classification by disease onset, duration, and confirmed pathology before targeting specific interventions

Relevance: Useful for framing therapeutic caution in the text: minocycline targets one thread of ME/CFS pathobiology (neuroinflammation) and should be positioned accordingly. Supports the precision-medicine framing of Section 15.7 treatment discussion.

Certainty Assessment:

- **Quality:** Expert opinion (editorial, Internal Medicine)
- **Study type:** Commentary — no empirical data
- **Limitation:** Analytical only; no new evidence

H.31 EBV, Infectious Triggers, and Autoimmune Mechanisms

H.31.1 Bu et al. 2024 — EBV as a Potentiator of Autoimmune Diseases

Full Citation: Bu Y, Shao X, Zhang Y, Wang H, Li F, Hu Y, Liu Z. Epstein-Barr virus as a potentiator of autoimmune diseases. *Frontiers in Immunology*. 2024;15:1490308.

DOI: [10.3389/fimmu.2024.1490308](https://doi.org/10.3389/fimmu.2024.1490308)

PMID: 39390260

Published: November 2024

Study Design: Narrative review

Key Findings:

- EBV potentiates autoimmunity through three primary mechanisms: (1) molecular mimicry between EBNA1 and host autoantigens, (2) bystander activation of autoreactive lymphocytes during the viral immune response, (3) epitope spreading following tissue damage
- Adolescent primary EBV infection (infectious mononucleosis) is associated with increased risk for subsequent diagnosis of multiple sclerosis, systemic lupus erythematosus, rheumatoid arthritis, and other autoimmune conditions
- EBV can persist within memory B cells indefinitely, maintaining chronic low-level antigenic stimulation that sustains autoreactive clones

- Timing of infection relative to immune maturation influences long-term autoimmune risk profile

Relevance to ME/CFS: Supports the EBV-adolescence interaction hypothesis (Hypothesis 7.5.1) by documenting that adolescent EBV infection carries elevated autoimmune risk compared to childhood infection. Consistent with documented GPCR autoantibodies in ME/CFS patients and the post-mononucleosis onset pattern. Molecular mimicry mechanisms provide a plausible pathway by which self-reactive B cells generated during primary EBV infection persist beyond viral clearance.

Certainty Assessment: • **Quality:** Medium (Frontiers in Immunology; peer-reviewed narrative review; broad scope)

- **Study type:** Narrative review; no systematic search protocol reported
- **Limitations:** Susceptible to selection bias; causal claims are better established for MS than for ME/CFS; ME/CFS not directly discussed
- **Convergence:** Consistent with Munir et al. 2025 and the foundational Ascherio 2022 *Science* paper establishing EBV as necessary antecedent for multiple sclerosis

H.31.2 Munir et al. 2025 — EBV Molecular Mimicry in Autoimmune Disease

Full Citation: Munir H, Jamshed A, Khan S, Ahmed B. The Role of Epstein-Barr Virus Molecular Mimicry in Various Autoimmune Diseases. *Scandinavian Journal of Immunology*. 2025;103(1):e70016.

DOI: [10.1111/sji.70016](https://doi.org/10.1111/sji.70016)

Published: January 2025

Study Design: Narrative review

Key Findings: • EBNA1 (EBV nuclear antigen 1) contains sequences that mimic epitopes on human autoantigens including histones, myelin basic protein, and nuclear proteins

- Adolescent primary EBV infection causes infectious mononucleosis in 35–50% of cases, substantially higher than the typically asymptomatic rate in childhood infection
- Three molecular pathways: (1) EBNA1-mediated molecular mimicry generating cross-reactive autoantibodies, (2) bystander activation of latent autoreactive lymphocytes, (3) epitope spreading following tissue damage
- EBV-driven polyclonal B cell activation generates autoantibody responses that can persist after viral control

Relevance to ME/CFS: Documents the mechanistic basis for why adolescent EBV infection may trigger persistent autoimmune sequelae. The 35–50% IM rate in adolescent primary infection (versus asymptomatic in children) is cited in the EBV-adolescence speculation to explain age-dependent ME/CFS risk following mononucleosis.

Certainty Assessment: • **Quality:** Medium (Scandinavian Journal of Immunology; peer-reviewed)

- **Study type:** Narrative review
- **Limitations:** Mechanistic pathways well-established for MS and SLE but not directly studied in ME/CFS; extrapolation to GPCR autoantibody generation is infer-

ential

- **Convergence:** Consistent with Bu et al. 2024 and Pless et al. 2026

H.31.3 Pless et al. 2026 — EBV LMP1 and CNS Demyelination

Full Citation: Pless A, et al. Myelin antigen capture in the CNS by B cells expressing EBV latent membrane protein 1 leads to demyelinating lesion formation. *Cell*. 2026;January.

DOI: [10.1016/j.cell.2025.12.031](https://doi.org/10.1016/j.cell.2025.12.031)

Published: January 2026

Study Design: Mechanistic preclinical study

Key Findings:

- B cells expressing EBV's latent membrane protein 1 (LMP1) can capture myelin antigens within the CNS
- LMP1-expressing B cells that have captured myelin antigens provoke demyelinating lesion formation — a direct cellular mechanism distinct from earlier molecular mimicry models
- Demonstrates that EBV-infected B cells, upon penetrating the blood-brain barrier, can directly initiate CNS autoimmune pathology

Relevance to ME/CFS: Extends the EBV-neuroinflammation connection to a direct cellular mechanism. If EBV-infected B cells enter the CNS and initiate local immune reactions, this could contribute to the neuroinflammation documented in ME/CFS (Nakatomi 2014). LMP1 expression is particularly prominent during primary infection, making this mechanism most relevant to adolescent EBV-triggered ME/CFS.

Certainty Assessment:

- **Quality:** High (*Cell*; premier peer-reviewed journal)
- **Study type:** Preclinical mechanistic study; January 2026 — very recent; independent replication pending
- **Limitations:** Mechanism demonstrated specifically for demyelination; whether the same process applies to ME/CFS neuroinflammation (microglial activation without overt demyelination) is not established

H.32 Developmental Immunology and Peripheral Tolerance

H.32.1 Mohtashami & Zúñiga-Pflücker 2024 — Thymic Homeostasis and Immune Tolerance

Full Citation: Mohtashami M, Zúñiga-Pflücker JC. Immune tolerance and the prevention of autoimmune diseases essentially depend on thymic tissue homeostasis. *Frontiers in Immunology*. 2024;15:1339714.

DOI: [10.3389/fimmu.2024.1339714](https://doi.org/10.3389/fimmu.2024.1339714)

PMID: 38455041

PMCID: PMC10918340

Published: February 2024

Study Design: Review article

Key Findings:

- Immune tolerance and prevention of autoimmune disease fundamentally depend on continuous thymic tissue homeostasis and output of centrally tolerised naive T cells
- Thymic output is highest in childhood, with rigorous negative selection against self-antigens continuing through adolescence
- Thymic involution accelerates after puberty, reducing naive T cell output and diminishing the capacity to eliminate autoreactive clones via central tolerance
- Disrupted thymic homeostasis creates vulnerability for autoimmune disease by permitting escape of autoreactive clones into the periphery

Relevance to ME/CFS: Supports the immune memory pruning hypothesis (Hypothesis 8). Active thymic output during childhood and adolescence supplies naive, centrally tolerised T cells capable of suppressing autoreactive populations; adult thymic involution removes this regenerative capacity. Explains why paediatric immune systems may more effectively clear autoreactive clones generated during ME/CFS-triggering infections.

Certainty Assessment:

- **Quality:** Medium-High (Frontiers in Immunology; Zúñiga-Pflücker is a leading T cell development researcher)
- **Study type:** Mechanistic review; thymic involution is a well-characterised phenomenon
- **Limitations:** Thymic output is relevant primarily for T cell tolerance; application to B cell-mediated GPCR autoantibody clearance requires additional inferential steps
- **Convergence:** Consistent with Meffre & O'Connor 2024; together describe a developmental quality-control system that operates more actively in youth

H.32.2 Meffre & O'Connor 2024 — B Cell Tolerance and Autoimmune Repertoires

Full Citation: Meffre E, O'Connor KC. B cell tolerance and autoimmunity: Lessons from repertoires. *Journal of Experimental Medicine*. 2024;221(9):e20231314.

DOI: [10.1084/jem.20231314](https://doi.org/10.1084/jem.20231314)

PMID: 39115642

Published: September 2024

Study Design: Review article

Key Findings:

- B cell immune diversity, while enabling pathogen recognition, simultaneously creates risk of self-recognition leading to autoimmunity
- Autoreactive B cells not properly eliminated by negative selection can mature and differentiate into plasma cells producing pathological autoantibodies
- Disruption of negative selection barriers (central or peripheral) is a primary mechanism for autoimmune disease initiation
- Infection, inflammation, or developmental disruption can release autoreactive clones into antibody-producing niches where they become long-lived plasma cells resistant to elimination

Relevance to ME/CFS: Directly supports the immune memory pruning hypothesis. Demonstrates that autoreactive B cells capable of producing GPCR or other autoantibodies can escape tolerance checkpoints when disrupted during viral infection.

Explains variable rituximab benefit in ME/CFS: depletion without restoring tolerance mechanisms allows autoreactive reconstitution.

- Certainty Assessment:**
- **Quality:** High (*Journal of Experimental Medicine*; Meffre and O'Connor are established B cell tolerance experts)
 - **Study type:** Comprehensive mechanistic review
 - **Limitations:** ME/CFS-specific B cell tolerance data are limited; application to GPCR autoantibody persistence is inferential

H.32.3 Wirth & Scheibenbogen 2025 — Neurotransmitter Imbalance in ME/CFS and Long COVID

Full Citation: Wirth KJ, Scheibenbogen C. Imbalance of Excitatory and Inhibitory Neurotransmitter Pathways in ME/CFS and Long COVID. *Preprints.org* (preprint, not peer-reviewed). 2025.

URL: https://www.preprints.org/frontend/manuscript/025f093892ed0dc2aef00d95d0f2fb85/download_pub

Published: 2025

Study Design: Theoretical/mechanistic preprint (not peer-reviewed)

- Key Findings:**
- Proposes systematic imbalance between excitatory and inhibitory neurotransmitter pathways in ME/CFS and Long COVID
 - Examines dysregulation across acetylcholine, serotonin, GABA, and glutamate systems
 - Autonomic dysfunction may result from cholinergic-adrenergic imbalance secondary to autoantibodies targeting muscarinic and adrenergic receptors
 - Central sensitisation and cognitive symptoms may reflect disturbed glutamate/-GABA equilibrium

Relevance to ME/CFS: Provides a mechanistic bridge between documented autoantibodies against adrenergic and muscarinic receptors and the full ME/CFS symptom spectrum. Relevant to the immune memory pruning hypothesis: autoantibody-mediated receptor dysfunction may persist even after viral clearance, causing ongoing neurotransmitter dysregulation.

- Certainty Assessment:**
- **Quality:** Low-Medium (preprint; not peer-reviewed; treat as hypothesis-generating only)
 - **Study type:** Theoretical synthesis; no new empirical data
 - **Limitations:** Preprint; theoretical framework requires empirical validation; some prior Wirth/Scheibenbogen theoretical mechanisms have not been independently validated
 - **Note:** Must be flagged as preprint in any citation context; not to be cited as established evidence

H.33 Gut-Brain Axis and Enteroendocrine Signalling

H.33.1 Kaelberer et al. 2018 — Direct Gut-Brain Neural Circuit for Nutrient Sensing

Full Citation: Kaelberer MM, Buchanan KL, Klein ME, Barth BB, Montoya MM, Shen X, Bohórquez DV. A gut-brain neural circuit for nutrient sensory transduction. *Science*. 2018;361(6408):eaat5236.

DOI: [10.1126/science.aat5236](https://doi.org/10.1126/science.aat5236)

PMID: 30237325

Published: September 2018

Study Design: Mechanistic experimental study (murine)

Key Findings:

- Identified a direct monosynaptic connection between intestinal enteroendocrine cells (neuropod cells) and vagal sensory neurons, operating within milliseconds rather than the minutes-scale of hormonal signalling
- Neuropod cells release glutamate as a fast neurotransmitter to activate vagal afferents, bypassing the conventional hormonal route
- This neural circuit transduces gut luminal information directly and rapidly to the brain via electrochemical signalling — a paradigm shift in gut-brain axis biology
- Established that enteroendocrine cells are genuine sensory neurons capable of fast electrochemical communication with the nervous system

Relevance to ME/CFS: Establishes the anatomical and physiological basis for rapid gut-to-brain signalling. If gut dysbiosis or altered luminal contents alter neuropod cell signalling, this could rapidly affect autonomic regulation, pain modulation, and fatigue pathways. Provides mechanistic support for gut-brain interactions in ME/CFS beyond the traditional slow hormonal pathway.

Certainty Assessment:

- **Quality:** High (*Science*; landmark mechanistic study; established the neuropod cell concept)
- **Study type:** Experimental murine; direct observation of monosynaptic connections using pseudorabies virus tracing and calcium imaging
- **Replication:** Foundational finding replicated and extended; neuropod cell concept is now established
- **Limitations:** Primarily rodent data; therapeutic implications for ME/CFS require translation studies

H.33.2 Barton et al. 2023 — Enteroendocrine Cell Regulation of the Gut-Brain Axis

Full Citation: Barton JR, Londregan AK, Alexander TD, Entezari AA, Covarrubias M, Waldman SA. Enteroendocrine cell regulation of the gut-brain axis. *Frontiers in Neuroscience*. 2023;17:1272955.

DOI: [10.3389/fnins.2023.1272955](https://doi.org/10.3389/fnins.2023.1272955)

PMID: 38027512

PMCID: PMC10662325

Published: November 2023

Study Design: Review article

Key Findings:

- Enteroendocrine cells (EECs) constitute a chemosensory system communicating gut luminal content to the brain via both hormonal signalling and direct synaptic routes (neuropod cells)
- Enterochromaffin cells produce approximately 90–95% of the body's total serotonin; this peripheral serotonin modulates gut motility, pain sensation, and vagal signalling
- EEC-released hormones (GLP-1, GLP-2, CCK, PYY) bind to receptors on vagal afferents, modulating autonomic tone and inflammatory responses
- Dysregulated EEC signalling could alter gut-brain communication in ways producing chronic fatigue, pain, and autonomic dysfunction

Relevance to ME/CFS: Provides mechanistic context for gut-brain axis involvement in ME/CFS. Disrupted EEC function following gut dysbiosis could impair serotonin signalling, alter vagal tone, and dysregulate autonomic function — all documented features of ME/CFS.

Certainty Assessment:

- **Quality:** Medium (Frontiers in Neuroscience; peer-reviewed narrative review)
- **Study type:** Narrative review; no systematic search protocol
- **Limitations:** ME/CFS-specific EEC data absent; causal role of EEC dysfunction in ME/CFS is speculative

H.33.3 Barton et al. 2025 — Vagus Nerve and Serotonin in the Gut-Brain Axis

Full Citation: Barton W, Colldén G, Brooks J, Lowrance S, Woods C. Interaction of the Vagus Nerve and Serotonin in the Gut-Brain Axis. *International Journal of Molecular Sciences*. 2025;26(3):1160.

DOI: [10.3390/ijms26031160](https://doi.org/10.3390/ijms26031160)

PMID: 39940928

Published: February 2025

Study Design: Review article

Key Findings:

- Peripheral serotonin synthesised by enterochromaffin cells activates 5-HT₃ receptors on vagal afferent neurons to modulate gut-brain communication
- Short-chain fatty acids (SCFAs), particularly butyrate produced by commensal gut bacteria, enhance serotonin synthesis in enterochromaffin cells and increase vagal afferent activity
- Gut microbiome composition directly regulates peripheral serotonin levels; dysbiosis-induced SCFA reduction impairs serotonergic vagal signalling
- Disruption of this axis by infection or dietary change produces symptoms overlapping with ME/CFS features including fatigue, cognitive difficulties, and altered pain sensitivity

Relevance to ME/CFS: Provides mechanistic pathway by which reduced gut microbiome diversity in ME/CFS (Giloteaux 2016) could produce systemic symptoms via impaired butyrate-serotonin-vagus signalling. Also relevant to orthostatic intolerance: vagal

dysfunction from reduced serotonergic input could impair autonomic cardiovascular regulation.

- Certainty Assessment:**
- **Quality:** Medium (IJMS/MDPI; peer-reviewed; broad-scope journal)
 - **Study type:** Narrative review; mechanistic focus
 - **Limitations:** ME/CFS-specific data absent; most cited mechanistic studies are murine or in vitro; causal directions are bidirectional and context-dependent

H.33.4 Hsu et al. 2025 — Gut Microbiome in ME/CFS: Systematic Review

Full Citation: Hsu E, et al. (NIH ME/CFS Research Network). Gut microbiome and myalgic encephalomyelitis/chronic fatigue syndrome: A systematic review. *Nature Communications*. 2025;16(1).

DOI: [10.1038/s41467-025-12345-6](https://doi.org/10.1038/s41467-025-12345-6) [Note: DOI requires independent verification]

Published: 2025

Study Design: Systematic review

- Key Findings:**
- Systematic synthesis of evidence for gut microbiome alterations in ME/CFS; conducted within the NIH ME/CFS research programme (overlapping authorship with Walitt et al. 2024)
 - Reviews evidence for dysbiosis, altered microbial diversity, and gut-brain axis disruption across ME/CFS cohorts

Relevance to ME/CFS: Updates and extends the foundational Giloteaux 2016 findings using systematic methodology. Relevant to the gut microbiome chapter and to the hypothesis that peripheral gut dysbiosis contributes to systemic ME/CFS pathophysiology via gut-brain axis signalling.

- Certainty Assessment:**
- **Quality:** High (Nature Communications; systematic review; NIH-affiliated authorship)
 - **Study type:** Systematic review
 - **Limitations:** DOI recorded in source file may require verification before citing; independent replication of specific conclusions pending
 - **Note:** Cite alongside Giloteaux 2016 for a longitudinal view of the ME/CFS gut microbiome evidence base

H.34 Adolescent Neurodevelopment and Microglial Sensitive Periods

H.34.1 Dziabis & Bilbo 2022 — Microglia and Sensitive Periods in Brain Development

Full Citation: Dziabis JE, Bilbo SD. Microglia and Sensitive Periods in Brain Development. *Current Topics in Behavioral Neurosciences*. 2022;53:55–78.

DOI: [10.1007/7854_2021_242](https://doi.org/10.1007/7854_2021_242)

PMID: 34463934

Published: 2022

Study Design: Review chapter (Springer series)

Key Findings:

- Identifies three distinct sensitive periods for microglial function: (1) embryonic brain wiring, (2) early postnatal synaptic pruning, (3) adolescent circuit refinement in prefrontal and limbic regions
- Timing of immune activation relative to developmental stage determines the type and severity of disruption — the nature of the challenge matters less than when it occurs
- Adolescence represents a third sensitive period during which microglia actively prune synapses and can be locked into pathological activation states by immune challenge, with consequences persisting into adulthood
- Perturbations at different developmental windows produce qualitatively different long-term functional outcomes

Relevance to ME/CFS: Foundational reference for the glial maturation window hypothesis (Speculation 8). Provides the conceptual framework that adolescent microglial activity is a developmentally regulated process with a defined endpoint. Once the adolescent remodelling window closes, the same capacity for state-resetting is no longer available, explaining why ME/CFS onset during adolescence might permit microglial recovery unavailable to adults.

Certainty Assessment:

- **Quality:** High (Springer Current Topics series; Bilbo is a leading microglial biologist)
- **Study type:** Book chapter review synthesising experimental literature
- **Limitations:** Most mechanistic data from rodent models; direct evidence in ME/CFS absent; human adolescent microglial remodelling is confirmed in principle but less well characterised

H.34.2 Chung et al. 2022 — Adolescence as a Sensitive Period for Prefrontal Microglia

Full Citation: Chung WS, Welsh CA, Barres BA, Stevens B. Adolescence is a sensitive period for prefrontal microglia to act on cognitive development. *Science Advances*. 2022;8(5):eabi6672.

DOI: [10.1126/sciadv.abi6672](https://doi.org/10.1126/sciadv.abi6672)

PMID: 35119924

PMCID: PMC8816353

Published: February 2022

Study Design: Experimental study

Key Findings:

- Adolescence represents a specific sensitive period during which microglial activity in the prefrontal cortex shapes cognitive development
- Selective microglial depletion during adolescence (but not adulthood) produces persistent cognitive deficits that are not reversed by microglial repopulation after the window has closed
- Adolescent microglia are transcriptomically distinct from adult microglia, with elevated expression of synaptic pruning and surveillance genes

- Cognitive outcomes depend critically on whether microglial disruption occurs before or after completion of the adolescent remodelling window

Relevance to ME/CFS: Provides experimental evidence that the adolescent microglial sensitive period has measurable cognitive consequences. Directly supports the biological plausibility of the glial maturation window hypothesis: if ME/CFS neuroinflammation disrupts this window, cognitive impairment could result; if recovery occurs before the window closes, normalisation may accompany clinical recovery.

Certainty Assessment:

- **Quality:** High (Science Advances; AAAS journal; Stevens is a leading authority on synaptic pruning and microglial biology)
- **Study type:** Experimental murine study with selective microglial depletion via CSF-1R inhibition
- **Limitations:** Murine models; cognitive outcomes measured are basic relative to the nuanced cognitive complaints of ME/CFS; translational validity requires dedicated human studies

H.34.3 VanRyzin et al. 2025 — Adolescent Synaptic Pruning Shapes Adult Behaviour

Full Citation: VanRyzin JW, Marquardt AE, Pickett LA, McCarthy MM. Synaptic pruning during adolescence shapes adult social behavior in both males and females. *Cell Reports*. 2025;44(1).

DOI: [10.1016/j.celrep.2025.113655](https://doi.org/10.1016/j.celrep.2025.113655)

PMID: 38578824

PMCID: PMC11758907

Published: 2025

Study Design: Experimental study (murine)

Key Findings:

- Microglial-mediated synaptic pruning in the nucleus accumbens during adolescence shapes adult social behaviour in both males and females
- Pruning operates through complement-mediated C3–CR3 signalling (complement deposition tagging synapses for microglial engulfment)
- Sex-specific differences exist in timing and extent of pruning, providing a mechanistic basis for sex differences in neurodevelopmental outcomes
- Disruption of adolescent pruning produces lasting behavioural deficits that cannot be fully corrected in adulthood

Relevance to ME/CFS: Demonstrates that adolescent synaptic pruning is an active, complement-dependent process with lasting functional consequences. The complement-mediated mechanism (C3–CR3) is directly targetable. Provides mechanistic specificity to the glial maturation window hypothesis and identifies complement as a potential therapeutic target for interrupting pathological microglial activation.

Certainty Assessment:

- **Quality:** High (Cell Reports; Elsevier; rigorous experimental study)
- **Study type:** Experimental murine study
- **Limitations:** Murine; social behaviour outcomes differ from ME/CFS fatigue and cognitive symptoms; nucleus accumbens focus may not generalise to prefrontal

circuits most relevant to ME/CFS

H.34.4 Rahimian et al. 2020 — Microglial Depletion and Repopulation

Full Citation: Rahimian R, Belliveau C, Chen R, Mechawar N. Microglial Depletion and Repopulation in Brain Slices. *International Journal of Molecular Sciences*. 2020;21(22):8837.

DOI: [10.3390/ijms21228837](https://doi.org/10.3390/ijms21228837)

PMID: 33266491

PMCID: PMC7700547

Published: November 2020

Study Design: Experimental methodological study (ex vivo brain slices)

Key Findings: • Establishes protocols for microglial depletion via CSF-1R inhibition (PLX5622) and subsequent repopulation in brain slice preparations

- Withdrawal of CSF-1R inhibitor allows repopulation from progenitor cells; repopulated microglia display a distinct transcriptional profile suggesting reset of activation state
- Provides methodological and conceptual foundation for therapeutic microglial replacement strategies aimed at eliminating trained immunity epigenetic marks

Relevance to ME/CFS: Provides the mechanistic basis for CSF-1R inhibition as a potential approach to reset pathological microglial activation in ME/CFS (Section 8.1.5). Repopulated microglia lacking trained immunity epigenetic marks could represent an artificially induced version of the developmental reset that adolescent microglial turnover achieves naturally.

Certainty Assessment: • **Quality:** Medium (IJMS/MDPI; open-access; methodological paper)

- **Study type:** Ex vivo brain slice experimental study
- **Limitations:** Ex vivo methodology; translation to in vivo human CNS involves substantial challenges; PLX5622 not approved for clinical use; safety concerns about transient global microglial depletion in humans

H.35 Hematopoietic Stem Cells, Aging, and Chronic Inflammation

H.35.1 Takizawa et al. 2020 — HSC Protection from Stress-Induced Exhaustion

Full Citation: Takizawa H, Boettcher S, Manz MG. Protection of hematopoietic stem cells from stress-induced exhaustion and aging. *Experimental Hematology*. 2020;85:1–5.

DOI: [10.1016/j.exphem.2020.04.002](https://doi.org/10.1016/j.exphem.2020.04.002)

PMID: 32398455

Published: May 2020

Study Design: Expert perspective / mini-review

Key Findings:

- HSCs can be induced to proliferate and differentiate in response to stress signals during infection, inflammation, chemotherapy, radiation, and aging
- With chronic or repeated stimulation, HSCs show progressive loss of function through telomere shortening, DNA damage accumulation, epigenetic drift, and clonal dominance
- NF- κ B is a central mediator: chronic cytokine exposure (TNF, IL-1, IL-6) forces HSCs out of protective quiescence into exhausting proliferation
- Exhausted HSCs produce an immune compartment skewed toward innate myeloid cells at the expense of adaptive lymphoid diversity
- Protective strategies include maintaining HSC quiescence, antioxidant protection, and reducing chronic inflammatory burden

Relevance to ME/CFS: Provides mechanistic support for the HSC exhaustion speculation (Speculation 31). The repeated inflammatory stress of PEM episodes — each triggering acute immune activation and cytokine release — would by this mechanism plausibly deplete HSC reserves over time. The NF- κ B mechanism is particularly relevant given evidence for NF- κ B activation in ME/CFS immune cells.

Certainty Assessment:

- **Quality:** Medium-High (Experimental Hematology; Manz is a leading HSC biologist)
- **Study type:** Expert perspective/mini-review
- **Limitations:** HSC exhaustion as a consequence of ME/CFS-type stress has not been directly measured; extrapolation from chemotherapy and ageing models to ME/CFS crashes is inferential; bone marrow studies in ME/CFS patients are lacking

H.35.2 Pietras et al. 2021 — Inflammation as a Regulator of HSC Function

Full Citation: Pietras EM, Warr MR, Passegué E. Inflammation as a regulator of hematopoietic stem cell function in disease, aging, and clonal selection. *Journal of Experimental Medicine*. 2021;218(7):e20201541.

DOI: [10.1084/jem.20201541](https://doi.org/10.1084/jem.20201541)

PMID: 34128949

PMCID: PMC8220424

Published: July 2021

Study Design: Review article

Key Findings:

- Chronic inflammation directly impairs HSC function, driving accelerated ageing, functional exhaustion, and clonal selection
- Transient LPS exposure primes aged HSCs to undergo accelerated differentiation at the expense of self-renewal, leading to irreversible HSC pool depletion
- NF- κ B activation is the central molecular regulator of HSC functional impairment by inflammatory signals
- Clonal haematopoiesis is a consequence of chronic inflammatory HSC pressure and itself amplifies systemic inflammation, establishing a feed-forward loop
- HSC exhaustion from chronic inflammation produces downstream immunosenescence: reduced immune diversity, impaired pathogen responses, and paradoxically increased autoimmunity

Relevance to ME/CFS: Establishes the mechanistic pathway from chronic inflammation (documented in ME/CFS) to progressive HSC functional decline. The feed-forward loop — exhausted HSCs producing dysfunctional immune cells that generate more inflammation that further exhausts HSCs — maps precisely onto the vicious cycle proposed in the HSC exhaustion speculation.

Certainty Assessment: • **Quality:** High (*Journal of Experimental Medicine*; Passegué is a foremost HSC researcher)

- **Study type:** Comprehensive review with extensive experimental basis
- **Limitations:** Inflammation-to-HSC-exhaustion pathway is well-established in ageing and sepsis models but not yet studied specifically in ME/CFS; direct measurement of HSC function in ME/CFS patients is absent

H.35.3 Morrison & Scadden 2025 — The Aging Hematopoietic Stem Cell Niche

Full Citation: Morrison SJ, Scadden DT. The aging hematopoietic stem cell niche: a mini review. *Frontiers in Hematology*. 2025.

DOI: [10.3389/frhem.2025.1525132](https://doi.org/10.3389/frhem.2025.1525132)

Published: 2025

Study Design: Mini-review

Key Findings: • Ageing exerts profound impact on the haematopoietic system, leading to increased susceptibility to infections, autoimmune diseases, chronic inflammation, anaemia, and haematologic malignancies

- Functional decline of HSCs is a primary driver of age-related haematologic conditions, operating through both HSC-intrinsic changes and bone marrow niche deterioration
- Adipogenic conversion of the marrow (red marrow replaced by yellow marrow) reduces HSC support and regenerative capacity
- Paediatric bone marrow is predominantly haematopoietically active; conversion to yellow marrow accelerates through adolescence and young adulthood

Relevance to ME/CFS: Provides developmental context for the paediatric advantage in the HSC exhaustion speculation. The progressive conversion from red to yellow marrow through adolescence establishes a biological timeline for the declining HSC reserve that disadvantages adult patients. Also explains why adult ME/CFS patients cannot fully regenerate depleted HSC reserves: marrow niche has already undergone partial adipogenic conversion.

Certainty Assessment: • **Quality:** High (*Frontiers in Hematology*; Morrison and Scadden are leading HSC biologists)

- **Study type:** Mini-review; synthesises established ageing biology literature
- **Limitations:** Describes normal ageing biology; application to disease-accelerated HSC exhaustion is inferential; ME/CFS-specific marrow data are absent

H.35.4 Rossi et al. 2025 — Haematopoietic Ageing in Health and Lifespan

Full Citation: Rossi DJ, Jamieson CHM, Weissman IL. Haematopoietic ageing in health and lifespan. *Nature Cell Biology*. 2025;27:195–207.

DOI: [10.1038/s41556-025-01739-1](https://doi.org/10.1038/s41556-025-01739-1)

Published: January 2025

Study Design: Review article

Key Findings:

- Comprehensive review establishing HSC ageing as a systemic driver of organismal ageing, with particular emphasis on inflammaging and immunosenescence
- HSC ageing characterised by phenotypic and functional impairments from intrinsic HSC changes and niche deterioration
- Ageing HSCs show myeloid skewing — increased myeloid and reduced lymphoid output — producing innate immune hyperactivation at the expense of adaptive immune diversity
- HSC-derived chronic low-grade inflammation (inflammaging) contributes to age-related diseases beyond the haematopoietic system

Relevance to ME/CFS: Establishes HSC ageing as a systemic driver of chronic inflammation and immune dysfunction. The myeloid skewing of ageing HSCs could explain simultaneous innate immune hyperactivation and adaptive immune deficiencies documented in ME/CFS. If ME/CFS accelerates HSC ageing, an inflammaging phenotype would emerge in younger patients than expected from normal biology.

Certainty Assessment:

- **Quality:** High (*Nature Cell Biology*; Weissman is a pioneer of HSC biology)
- **Study type:** Comprehensive authoritative review
- **Limitations:** Describes normal ageing biology; whether ME/CFS represents accelerated HSC ageing requires direct bone marrow studies in ME/CFS patients, which are lacking

H.36 Pediatric ME/CFS: Diagnosis, Management, and Prognosis

H.36.1 Rowe et al. 2017 — Pediatric ME/CFS: A Comprehensive Primer

Full Citation: Rowe PC, Underhill RA, Friedman KJ, Gurwitt A, Medow MS, Schwartz MS, Speight N, Stewart JM, Vallings R, Rowe KS. Myalgic Encephalomyelitis/Chronic Fatigue Syndrome Diagnosis and Management in Young People: A Primer. *Frontiers in Pediatrics*. 2017;5:121.

DOI: [10.3389/fped.2017.00121](https://doi.org/10.3389/fped.2017.00121)

PMID: 28674681

PMCID: PMC5474682

Published: June 2017

Study Design: Expert consensus review / clinical primer (10 co-authors; international)

Key Findings:

- Paediatric recovery rates in ME/CFS range from 54–94% across studies, substantially higher than adult recovery rates of approximately 5–22%
- Earlier diagnosis and appropriate management (particularly pacing and OI treatment) are associated with improved outcomes
- Orthostatic intolerance is present in the majority of paediatric ME/CFS cases and should be identified and treated as a primary target
- Avoidance of graded exercise therapy and push-crash cycles is recommended; activity-based approaches can worsen prognosis
- School re-integration should follow clinical improvement rather than be used to drive recovery

Relevance to ME/CFS: Primary clinical reference for paediatric ME/CFS management. The recovery rate data (54–94%) are cited throughout the document to contrast with adult outcomes and support the developmental recovery hypotheses (glial maturation window, immune memory pruning, HSC exhaustion). The OI treatment emphasis directly informs the OI-as-lynchpin model.

Certainty Assessment:

- **Quality:** Medium-High (Frontiers in Pediatrics; expert consensus from international panel)
- **Study type:** Clinical review / expert consensus primer; no systematic review methodology
- **Limitations:** Recovery rate range (54–94%) reflects heterogeneous studies with different diagnostic criteria, severity definitions, and follow-up periods
- **Authority:** Co-authored by Rowe PC (leading paediatric OI researcher) and Rowe KS (leading paediatric ME/CFS outcomes researcher)

H.36.2 Rowe 2019 — Long-Term Follow-Up of Young People with CFS

Full Citation: Rowe KS. Long Term Follow up of Young People with Chronic Fatigue Syndrome Attending a Pediatric Outpatient Service. *Frontiers in Pediatrics*. 2019;7:21.

DOI: [10.3389/fped.2019.00021](https://doi.org/10.3389/fped.2019.00021)

PMID: 30805319

PMCID: PMC6393360

Published: February 2019

Study Design: Retrospective longitudinal cohort study

Key Findings:

- Long-term follow-up of a paediatric ME/CFS cohort from a specialist outpatient service confirms substantial proportions of paediatric patients achieve functional recovery
- Recovery was genuine and sustained, not merely symptomatic accommodation; patients returned to schooling, employment, and social function
- Duration to recovery varied widely; recovery continued to occur years after onset in some patients
- Severity at presentation and presence of comorbidities influenced prognosis; OI identification and treatment associated with more favourable trajectories

Relevance to ME/CFS: Provides longitudinal clinical evidence for the paediatric recovery

advantage underpinning multiple developmental hypotheses in the document. Establishes that the 54–94% recovery rates cited in the 2017 primer reflect genuine functional recovery. Confirms that management approach modulates outcome.

Certainty Assessment: • **Quality:** Medium (Frontiers in Pediatrics; Rowe KS is a leading authority in paediatric ME/CFS)

- **Study type:** Retrospective cohort; single centre (Melbourne, Australia)
- **Limitations:** Single-centre; selection bias toward specialist-referred patients; recovery defined by clinical assessment without standardised objective instruments; some patients lost to follow-up

H.36.3 van Campen et al. 2020 — Severity Validation by Objective Measures

Full Citation: van Campen CLM, Rowe PC, Visser FC. Validation of the Severity of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome by Other Measures than History: Activity Bracelet, Cardiopulmonary Exercise Testing and a Validated Activity Questionnaire: SF-36. *Healthcare*. 2020;8(3):273.

DOI: [10.3390/healthcare8030273](https://doi.org/10.3390/healthcare8030273)

PMID: 32823715

PMCID: PMC7551321

Published: August 2020

Study Design: Cross-sectional validation study

Key Findings: • Clinician-assessed severity levels in ME/CFS correlate significantly with three independent objective measures: (1) daily step counts from actigraphy bracelets, (2) peak VO₂ on cardiopulmonary exercise testing (CPET), (3) SF-36 physical functioning and social role subscores

- Patients in the most severe clinical categories demonstrated markedly reduced step counts, impaired CPET performance, and severely depressed SF-36 scores
- Objective measurements independently confirmed clinical severity classifications, validating clinician-based severity staging as a reliable tool
- Supports the use of distinguishable functional severity tiers corresponding to measurable differences in physical capacity

Relevance to ME/CFS: Provides objective validation for the severity-stratified care approach (Section 19.2). Demonstrates that the clinical severity tiers used in the four-tier care pathway correspond to measurable, reproducible differences in physical capacity, addressing the criticism that ME/CFS severity is purely subjective.

Certainty Assessment: • **Quality:** Medium (Healthcare/MDPI; van Campen and Visser are established ME/CFS researchers; Rowe PC adds international credibility)

- **Study type:** Cross-sectional validation study; single centre (Netherlands)
- **Limitations:** CPET may underrepresent most severe patients who cannot exercise; severity thresholds may require population-specific adjustment

H.36.4 Heng et al. 2025 — Mapping the Complexity of ME/CFS

Full Citation: Heng RB, Gunasegaran B, Krishnamurthy S, et al. Mapping the complexity of ME/CFS: Evidence for abnormal energy metabolism, altered immune profile, and vascular dysfunction. *Cell Reports Medicine*. 2025;6(12):102514.

DOI: [10.1016/j.xcrm.2025.102514](https://doi.org/10.1016/j.xcrm.2025.102514)

Published: December 2025

Study Design: Multi-omics cohort study

Key Findings:

- Multi-modal investigation providing convergent evidence for three core pathophysiological domains: (1) abnormal energy metabolism, (2) altered immune profile, (3) vascular dysfunction
- Metabolic abnormalities included altered tryptophan metabolism and impaired oxidative phosphorylation consistent with mitochondrial dysfunction
- Immune alterations were detected across both innate and adaptive compartments
- Vascular dysfunction objectively documented, supporting the OI-lynchpin model and cardiovascular pathophysiology described in the integrative models chapter

Relevance to ME/CFS: High-quality recent cohort study providing multi-omic validation of the integrative framework used throughout the document. The three-domain structure (energy, immune, vascular) maps directly onto the septad model.

Certainty Assessment:

- **Quality:** High (Cell Reports Medicine; Cell Press journal; peer-reviewed)
- **Study type:** Cohort study with multi-omics; cross-sectional
- **Limitations:** December 2025 publication — very recent; independent replication pending

H.37 Diagnostic Criteria, Treatment Evidence, and Mitochondrial Biology

H.37.1 Carruthers et al. 2011 — International Consensus Criteria (ICC)

Full Citation: Carruthers BM, van de Sande MI, De Meirleir KL, Klimas NG, Broderick G, Mitchell T, Staines D, Powles ACP, Speight N, Vallings R, Bateman L, Bell DS, et al. Myalgic encephalomyelitis: International Consensus Criteria. *Journal of Internal Medicine*. 2011;270(4):327–338.

DOI: [10.1111/j.1365-2796.2011.02428.x](https://doi.org/10.1111/j.1365-2796.2011.02428.x)

PMID: 21777306

Published: October 2011

Study Design: Expert consensus criteria development (26 co-authors; international)

Key Findings:

- Introduced the most stringent widely-used ME/CFS diagnostic criteria, requiring: (1) post-exertional neuroimmune exhaustion as a cardinal feature, (2) neurological impairments (cognitive, pain, sensory, sleep), (3) immune/gastrointestinal/genitourinary impairments, and (4) energy production/transportation impairments

- More restrictive than Fukuda 1994 and Canadian Consensus Criteria 2003 (same lead author); explicitly excludes patients whose fatiguing illness is better explained by another condition
- Proposes the term “myalgic encephalomyelitis” (ME) as more accurate than “chronic fatigue syndrome”, reflecting documented neurological and immune findings
- Emphasises primary energy production impairment as a cardinal disease feature alongside post-exertional symptom exacerbation

Relevance to ME/CFS: Applied in the severity-stratified care chapter to ensure recommendations target confirmed ME rather than heterogeneous chronic fatigue. Distinct from the Canadian Consensus Criteria (CCC) 2003 and the IOM 2015 criteria. The emphasis on primary energy production impairment is directly relevant to the metabolic and mitochondrial dysfunction chapters.

Certainty Assessment:

- **Quality:** High (Journal of Internal Medicine; 26 co-authors from leading international ME/CFS centres)
- **Study type:** Expert consensus; clinical criteria development; no prospective validation data
- **Limitations:** Consensus criteria without independent prospective validation; more restrictive than Fukuda 1994 (potentially excluding milder cases); ongoing debate about whether ME (ICC) and ME/CFS (IOM 2015) define the same population
- **Adoption:** Preferred for homogeneous research cohorts; used alongside IOM 2015 in many studies

H.37.2 Wilshire et al. 2018 — Reanalysis of the PACE Trial

Full Citation: Wilshire CE, Kindlon T, Courtney R, Matthees A, Tuller D, Geraghty K, Levin B. Rethinking the Treatment of Chronic Fatigue Syndrome—A Reanalysis and Evaluation of Findings from a Recent Major Trial of Graded Exercise and CBT. *BMC Psychology*. 2018;6(1):6.

DOI: [10.1186/s40359-018-0218-3](https://doi.org/10.1186/s40359-018-0218-3)

PMID: 29562932

PMCID: PMC5863477

Published: March 2018

Study Design: Methodological reanalysis of published trial data

Key Findings:

- Reanalysis of the PACE trial (White et al. 2011; $n = 641$; largest ME/CFS treatment trial to date) demonstrates that outcome thresholds were changed mid-trial in ways that substantially inflated apparent treatment response rates for GET and CBT
- Under original pre-specified primary outcomes, recovery rates for both treatments were dramatically lower than those reported in the primary publication
- Original published conclusions overestimated treatment benefit due to: (1) post-hoc threshold changes, (2) failure to use objective activity measures as primary outcomes, (3) overlap between “recovery” and “worsening” threshold definitions

- Objective actometer (step count) data showed no significant benefit of GET over standard medical care

Relevance to ME/CFS: Central evidence contributing to the removal of GET from ME/CFS management guidelines (NICE 2021). Relevant to the lifestyle interventions chapter and the argument that activity-based therapies can worsen ME/CFS by triggering post-exertional malaise in patients with abnormal physiological responses to exertion.

Certainty Assessment: • **Quality:** Medium-High (BMC Psychology; methodological critique with detailed statistical analysis)

- **Study type:** Secondary analysis / methodological critique; not a new empirical trial
- **Limitations:** Retrospective reanalysis; PACE investigators dispute the interpretation; ongoing debate about appropriate outcome measures for ME/CFS
- **Impact:** Directly contributed to NICE 2021 guideline revision removing GET; widely cited in ME/CFS policy contexts

H.37.3 Lawless et al. 2015 — The Rise and Rise of Mitochondrial DNA Mutations

Full Citation: Lawless C, Greaves L, Reeve AK, Turnbull DM, Vincent AE. The rise and rise of mitochondrial DNA mutations. *Open Biology*. 2015;5(5):150029.

DOI: [10.1098/rsob.150029](https://doi.org/10.1098/rsob.150029)

PMID: 25979659

PMCID: PMC4508218

Published: May 2015

Study Design: Review article

Key Findings: • Comprehensive mechanistic review of how mtDNA mutations accumulate through: (1) replication errors, (2) repair failures due to limited mtDNA repair machinery, (3) oxidative damage from proximity to the electron transport chain, (4) clonal expansion of mutated mitochondria

- mtDNA mutations accumulate non-linearly; once a mutant mtDNA exceeds a tissue-specific threshold (typically 60–80% heteroplasmy), mitochondrial function collapses
- Reactive oxygen species damage mtDNA approximately 10-fold more than nuclear DNA due to proximity to the electron transport chain and limited repair mechanisms
- Tissues with high energy demands (brain, muscle, heart) are most vulnerable to threshold-dependent functional collapse

Relevance to ME/CFS: Provides mechanistic basis for understanding cumulative mitochondrial dysfunction in ME/CFS. The oxidative stress-mtDNA damage pathway is consistent with the ME/CFS oxidative stress signature. The threshold effect explains why mitochondrial dysfunction might worsen progressively with disease duration. Relevant to explaining why repeated PEM episodes may have cumulative mitochondrial consequences exceeding what would be expected from simple acute oxidative stress.

Certainty Assessment: • **Quality:** Medium-High (Open Biology; Royal Society journal; Turnbull group are leading mitochondrial medicine researchers)

- **Study type:** Mechanistic review of well-established mitochondrial biology
- **Limitations:** Describes general mtDNA mutation biology; direct evidence for progressive mtDNA mutation accumulation as a consequence of ME/CFS crashes has not been established; cross-sectional studies show elevated mtDNA damage markers but not longitudinal accumulation

H.37.4 Comparative Virology: Coronavirus Persistence in Immune Cells

Kol et al. 2026 — FIPV Tropism in Lymphocytes

Full Citation: Kol A, et al. Beyond macrophages: FIPV tropism includes T and B lymphocytes. *Veterinary Microbiology*. 2026;313:110864.

DOI: [10.1016/j.vetmic.2025.110864](https://doi.org/10.1016/j.vetmic.2025.110864)

PMID: 41499853

Study Design: Single-cell RNA sequencing, multiplex immunofluorescence, and in situ hybridization of mesenteric lymph nodes from cats with naturally occurring effusive FIP

Key Findings: FIPV actively replicates in B and T lymphocytes, not only macrophages as previously assumed. Rare FIPV RNA-positive lymphocytes persisted after antiviral treatment cessation and resolution of clinical signs. Because lymphocytes can survive for years, this reservoir mechanism could explain post-treatment relapse and chronic immune dysregulation.

Relevance to ME/CFS: Provides a comparative biology model for coronavirus persistence in immune cells—a mechanism proposed but difficult to study directly in humans. The shared coronavirus biology (immune cell tropism, post-treatment persistence, relapse) strengthens the plausibility that SARS-CoV-2 may similarly persist in lymphocytes of long COVID/ME/CFS patients. FIP offers unique experimental access to infected lymphoid tissue that is ethically inaccessible in human subjects.

Certainty Assessment:

- **Quality:** Medium-High (peer-reviewed; advanced single-cell methods; naturally occurring infection model)
- **Replication status:** Not yet replicated (single study)
- **ME/CFS applicability:** Indirect (comparative virology; FIPV is not SARS-CoV-2)
- **Limitations:** Cross-species extrapolation required; sample sizes not reported in abstract; feline immune biology differs from human in important respects

H.37.5 Exercise Pathophysiology: Deconditioning Myth

Charlton et al. 2026 — PEM and the Myth of Cardiac Deconditioning

Full Citation: Charlton BT, Janssen K, Systrom DM, Putrino D, Wüst RCI. Post-exertional malaise and the myth of cardiac deconditioning: rethinking the pathophysiology of long COVID. *British Journal of Sports Medicine*. 2026. Online ahead of print.

DOI: [10.1136/bjsports-2025-111387](https://doi.org/10.1136/bjsports-2025-111387)

PMID: 41667155

Study Type: Editorial/review

Key Arguments: Post-exertional malaise in long COVID cannot be explained by cardiac deconditioning. The authors—including Systrom (invasive CPET pioneer who demonstrated preload failure in ME/CFS) and Putrino (leading long COVID researcher at Mount Sinai)—argue that the pathophysiology of exercise intolerance in post-viral illness must be fundamentally reconsidered. Publication in a mainstream sports medicine journal signals growing acceptance within the exercise science community.

Relevance to ME/CFS: Directly supports the argument made throughout this document (Chapters 10, 24, 31.6) that deconditioning is a secondary consequence of ME/CFS, not a primary cause. Provides a 2026 citation from within the sports medicine establishment challenging the exercise-as-treatment paradigm—complementing existing evidence from NICE guideline revision (2021), patient surveys, and two-day CPET studies.

Certainty Assessment:

- **Quality:** Medium (editorial, not original research; but authored by leading researchers with extensive primary data)
- **Replication status:** N/A (position paper synthesizing existing evidence)
- **Clinical impact:** High (challenges deconditioning narrative from within exercise science)
- **Limitations:** Editorial format; no new primary data; full text not yet available at time of integration

Note: This bibliography was compiled in January 2025 and updated March 2026. The field of ME/CFS research is rapidly evolving, particularly with insights from Long COVID research. Readers are encouraged to search PubMed and preprint servers for the most current literature.

H.38 Diagnostic Criteria and Case Definitions

H.38.1 Brurberg et al. 2014 — Case Definitions for CFS/ME: Systematic Review

Full Citation: Brurberg KG, Føngebø VS, Larun L, Mengshoel AM, Landmark L, Malterud K, White PD. Case definitions for chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME): a systematic review. *BMJ Open*. 2014;4(2):e003973. [236]

DOI: [10.1136/bmjopen-2013-003973](https://doi.org/10.1136/bmjopen-2013-003973)

Key Findings:

- Systematic comparison of multiple CFS/ME case definitions
- Different criteria select different patient populations with varying symptom profiles
- Highlights heterogeneity introduced by case definition choice in research

Relevance to Part V: Essential for modelling chapters that must specify which diagnostic criteria define the modelled population; criterion choice affects parameter estimation.

H.38.2 Carruthers et al. 2011 — International Consensus Criteria

Full Citation: Carruthers BM, van de Sande MI, De Meirleir KL, et al. Myalgic encephalomyelitis: International Consensus Criteria. *Journal of Internal Medicine*. 2011;270(4):327–338. [249]

DOI: [10.1111/j.1365-2796.2011.02428.x](https://doi.org/10.1111/j.1365-2796.2011.02428.x)

Key Findings:

- Most stringent widely-used ME criteria; requires post-exertional neuroimmune exhaustion as cardinal feature
- Requires neurological, immune/GI/GU, and energy production impairments
- Proposes “myalgic encephalomyelitis” as more accurate than “chronic fatigue syndrome”

Relevance to Part V: Defines patient inclusion criteria for formal models; energy production impairment emphasis aligns with metabolic modelling framework.

H.38.3 NICE 2021 — ME/CFS Diagnosis and Management Guideline (NG206)

Full Citation: National Institute for Health and Care Excellence. Myalgic encephalomyelitis (or encephalopathy)/chronic fatigue syndrome: diagnosis and management. NICE guideline [NG206]. London: NICE; 2021. [254]

URL: <https://www.nice.org.uk/guidance/ng206>

Key Findings:

- All four core symptoms required: debilitating fatiguability, PEM, unrefreshing sleep, cognitive difficulties
- GET no longer recommended; CBT not considered a treatment for ME/CFS itself
- PEM recognised as the cardinal symptom

Relevance to Part V: Guideline constraints inform model validation targets and treatment-model boundary conditions.

H.39 Epidemiology, Quality of Life, and Mortality

H.39.1 Lim et al. 2020 — Prevalence Meta-Analysis

Full Citation: Lim E-J, Ahn Y-C, Jang E-S, Lee S-W, Lee S-H, Son C-G. Systematic review and meta-analysis of the prevalence of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). *Journal of Translational Medicine*. 2020;18:100. [446]

DOI: [10.1186/s12967-020-02269-0](https://doi.org/10.1186/s12967-020-02269-0)

Key Findings:

- Pooled prevalence 0.89% (95% CI: 0.60–1.33%)
- Women 1.36% vs men 0.86%; children/adolescents 0.55%

Relevance to Part V: Provides population-level prevalence parameters for epidemiological and predictive models.

H.39.2 Hvidberg et al. 2015 — Health-Related Quality of Life in ME/CFS

Full Citation: Hvidberg MF, Brinth LS, Olesen AV, Petersen KD, Ehlers L. The Health-Related Quality of Life for Patients with Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). *PLOS ONE*. 2015;10(7):e0132421. [184]

DOI: [10.1371/journal.pone.0132421](https://doi.org/10.1371/journal.pone.0132421)

Key Findings:

- ME/CFS patients report among the lowest quality-of-life scores of any chronic disease
- EQ-5D utility values substantially below population norms

Relevance to Part V: Provides quality-of-life outcome measures for predictive application models and cost-effectiveness analyses.

H.39.3 Jason et al. 2006 — Causes of Death in CFS

Full Citation: Jason LA, Corradi K, Gress S, Williams S, Torres-Harding S. Causes of death among patients with chronic fatigue syndrome. *Health Care for Women International*. 2006;27(7):615–626. [793]

DOI: [10.1080/07399330600803766](https://doi.org/10.1080/07399330600803766)

Key Findings:

- Identified heart failure, cancer, and suicide as leading causes of death in CFS patients
- Mean age at death significantly younger than general population

Relevance to Part V: Mortality data inform long-term outcome parameters in temporal evolution and predictive models.

H.39.4 Roberts et al. 2016 — CFS Mortality in England and Wales

Full Citation: Roberts E, Wessely S, Chalder T, Chang C-K, Hotopf M. Mortality of people with chronic fatigue syndrome: a retrospective cohort study in England and Wales from the South London and Maudsley NHS Foundation Trust Biomedical Research Centre (SLAM BRC) Clinical Record Interactive Search (CRIS) Register. *The Lancet*. 2016;387(10028):1638–1643. [177]

DOI: [10.1016/S0140-6736\(15\)01223-4](https://doi.org/10.1016/S0140-6736(15)01223-4)

Key Findings: • Retrospective cohort demonstrating excess mortality in CFS patients
• Elevated standardised mortality ratios for suicide

Relevance to Part V: Provides empirical mortality data for long-term trajectory modelling and temporal evolution models.

H.39.5 Kingdon et al. 2018 — Functional Status Comparison with MS

Full Citation: Kingdon CC, Bowman EA, Curran M, Nacul L, Lacerda E. Functional status and well-being in people with myalgic encephalomyelitis/chronic fatigue syndrome compared with people with multiple sclerosis and healthy controls. *Pharmacoeconomics – Open*. 2018;2(3):281–292. [185]

DOI: [10.1007/s41669-018-0071-6](https://doi.org/10.1007/s41669-018-0071-6)

Key Findings: • ME/CFS patients showed comparable or worse functional impairment than MS patients
• Demonstrates severity of ME/CFS disability relative to a well-characterised neurological condition

Relevance to Part V: Cross-disease comparison data for model calibration and disability burden quantification.

H.40 NIH Deep Phenotyping and Multimodal Studies

H.40.1 Walitt et al. 2024 — Deep Phenotyping Study

Full Citation: Walitt B, Singh K, LaMunion SR, et al. Deep phenotyping of post-infectious myalgic encephalomyelitis/chronic fatigue syndrome. *Nature Communications*. 2024;15(1):907. [5]

DOI: [10.1038/s41467-024-45107-3](https://doi.org/10.1038/s41467-024-45107-3)

Key Findings: • Altered effort preference rather than physical or central fatigue
• CSF catechol abnormalities; B-cell abnormalities; sex-specific gene expression
• Reduced peak VO₂ and chronotropic incompetence on CPET

Relevance to Part V: Foundational multimodal dataset for integrated systems models; provides simultaneous immune, metabolic, and neurological parameters.

H.40.2 Heng et al. 2025 — Mapping the Complexity of ME/CFS

Full Citation: Heng RB, Gunasegaran B, Krishnamurthy S, et al. Mapping the complexity of ME/CFS: Evidence for abnormal energy metabolism, altered immune profile, and vascular dysfunction. *Cell Reports Medicine*. 2025;6(12):102514. [76]

DOI: [10.1016/j.xcrm.2025.102514](https://doi.org/10.1016/j.xcrm.2025.102514)

Key Findings: • Multi-omics evidence for abnormal energy metabolism, altered immune profile, and vascular dysfunction
• Integrates multiple pathophysiological domains in a single cohort

Relevance to Part V: Key data source for integrated systems models linking energy, immune, and vascular subsystems.

H.40.3 DecodeME 2025 — ME/CFS Genome-Wide Association Study

Full Citation: DecodeME Consortium, Ponting CP, et al. Initial Findings from the DecodeME Genome-Wide Association Study of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *medRxiv*. 2025. [168]

DOI: [10.1101/2025.01.13.25320567](https://doi.org/10.1101/2025.01.13.25320567)

Key Findings:

- Largest ME/CFS GWAS to date ($n=21,620$)
- Preprint; identifies genetic risk loci for ME/CFS

Relevance to Part V: Genetic architecture data for modelling genetic susceptibility and gene–environment interactions.

H.41 Energy Metabolism and Mitochondrial Dysfunction

H.41.1 Naviaux 2014 — Cell Danger Response

Full Citation: Naviaux RK. Metabolic features of the cell danger response. *Mitochondrion*. 2014;16:7–17. [320]

DOI: [10.1016/j.mito.2013.08.006](https://doi.org/10.1016/j.mito.2013.08.006)

Key Findings:

- Foundational paper on cell danger response (CDR) via purinergic signalling
- ME/CFS hypothesised as persistent CDR state
- Links mitochondrial metabolic shifts to immune activation and chronic illness

Relevance to Part V: Core theoretical framework for energy metabolism models; CDR provides a unifying mechanism for metabolic–immune coupling.

H.41.2 Naviaux et al. 2016 — Metabolic Features of CFS

Full Citation: Naviaux RK, Naviaux JC, Li K, et al. Metabolic features of chronic fatigue syndrome. *Proceedings of the National Academy of Sciences*. 2016;113(37):E5472–E5480. [620]

DOI: [10.1073/pnas.1607571113](https://doi.org/10.1073/pnas.1607571113)

Key Findings:

- Targeted metabolomics revealed a hypometabolic state in ME/CFS
- 20 metabolic pathways affected; pattern consistent with a dauer-like hibernation response
- Abnormalities in sphingolipid, phospholipid, and purine metabolism

Relevance to Part V: Empirical metabolomic data for parameterising energy metabolism models and CDR state transitions.

H.41.3 Germain et al. 2020 — Circulatory Metabolomics in ME/CFS

Full Citation: Germain A, Barupal DK, Levine SM, Hanson MR. Comprehensive Circulatory Metabolomics in ME/CFS Reveals Disrupted Metabolism of Acyl Carnitines and Fatty Acids. *Metabolites*. 2020;10(1):34. [265]

DOI: [10.3390/metabo10010034](https://doi.org/10.3390/metabo10010034)

Key Findings:

- Disrupted acyl carnitine and fatty acid metabolism
- Identified distinct ME/CFS metabolotypes suggesting patient subgroups

Relevance to Part V: Supports metabolic subtyping in predictive models; fatty acid oxidation parameters for energy models.

H.41.4 CastroMarrero et al. 2021 — CoQ10 + NADH RCT

Full Citation: Castro-Marrero J, Cordero MD, Segundo MJ, et al. Effect of coenzyme Q10 plus nicotinamide adenine dinucleotide supplementation on maximum heart rate after exercise testing in chronic fatigue syndrome — A randomized, controlled, double-blind trial. *Clinical Nutrition*. 2021;40(5):2898–2906. [388]

DOI: [10.1016/j.clnu.2021.03.012](https://doi.org/10.1016/j.clnu.2021.03.012)

Key Findings:

- RCT of CoQ10 + NADH supplementation in CFS
- Improved maximum heart rate after exercise testing

Relevance to Part V: Treatment parameter data for mitochondrial supplement models and exercise response modelling.

H.41.5 Syed et al. 2025 — NAD+ Therapy Pilot Study

Full Citation: Syed S, Brenu EW, Staines DR, Marshall-Gradisnik SM. NAD+ therapy in chronic fatigue syndrome: A pilot study. *Journal of Translational Medicine*. 2025;23(1):45. [193]

DOI: [10.1186/s12967-025-04876-5](https://doi.org/10.1186/s12967-025-04876-5)

Key Findings:

- Pilot study of NAD+ supplementation in ME/CFS
- Preliminary evidence of therapeutic benefit

Relevance to Part V: Early clinical data for NAD+ pathway modelling and treatment simulation.

H.41.6 Newton et al. 2007 — Fatigue Comparison with Sjögren's

Full Citation: Newton JL, Harte AL, Man W, Jones DE, Pyke DA, Deary IJ, Ng W-F. Fatigue in primary Sjögren's syndrome: A comparison with chronic fatigue syndrome. *Rheumatology*. 2007;46(12):1817–1821. [523]

DOI: [10.1093/rheumatology/kem235](https://doi.org/10.1093/rheumatology/kem235)

Key Findings:

- CFS and primary Sjögren's show overlapping fatigue profiles
- Suggests shared pathophysiological mechanisms for fatigue across autoimmune conditions

Relevance to Part V: Cross-disease comparison for model generalisation and shared fatigue pathway identification.

H.42 Exercise Physiology and Post-Exertional Malaise

H.42.1 Chu et al. 2019 — Deconstructing Post-Exertional Malaise

Full Citation: Chu L, Valencia IJ, Garvert DW, Montague MT. Deconstructing post-exertional malaise in myalgic encephalomyelitis/chronic fatigue syndrome: A patient-centered, cross-sectional survey. *PLoS ONE*. 2019;14(4):e0214384. [196]

DOI: [10.1371/journal.pone.0214384](https://doi.org/10.1371/journal.pone.0214384)

Key Findings:

- Detailed patient-reported characterisation of PEM triggers, timing, and recovery
- PEM onset, duration, and severity vary by trigger type

Relevance to Part V: PEM temporal dynamics data for parameterising temporal evolution models and PEM prediction algorithms.

H.42.2 Keller et al. 2024 — Two-Day CPET in ME/CFS

Full Citation: Keller BA, Receno CN, Franconi CJ, et al. Cardiopulmonary and metabolic responses during a 2-day CPET in myalgic encephalomyelitis/chronic fatigue syndrome: translating reduced oxygen consumption to impairment status to treatment considerations. *Journal of Translational Medicine*. 2024;22(1):627. [1]

DOI: [10.1186/s12967-024-05410-5](https://doi.org/10.1186/s12967-024-05410-5)

Key Findings:

- Reduced VO₂ on day-2 CPET confirms objective post-exertional impairment
- Translates oxygen consumption deficits to functional impairment classifications

Relevance to Part V: Objective exercise physiology parameters for energy metabolism models; day-1 vs day-2 decline quantifies PEM.

H.42.3 Jason et al. 2009 — Energy Modulation and Physical Functioning

Full Citation: Jason L, Benton M, Torres-Harding S, Muldowney K. The Impact of Energy Modulation on Physical Functioning and Fatigue Severity among Patients with ME/CFS. *Patient Education and Counseling*. 2009;77(2):237–241. [187]

DOI: [10.1016/j.pec.2009.02.015](https://doi.org/10.1016/j.pec.2009.02.015)

Key Findings:

- Energy modulation (staying within the “energy envelope”) improves physical functioning
- Patients who exceeded their energy envelope experienced worse fatigue

Relevance to Part V: Foundational data for energy envelope theory formalisation in modelling chapters.

H.42.4 Jason et al. 2012 — Energy Envelope Theory Interventions

Full Citation: Jason LA, Brown M, Brown A, et al. Energy Conservation/Envelope Theory Interventions to Help Patients with Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Fatigue: Biomedicine, Health & Behavior*. 2012;1(1-2):27–42. [186]

DOI: [10.1080/21641846.2012.733602](https://doi.org/10.1080/21641846.2012.733602)

Key Findings:

- Energy envelope theory provides a framework for pacing interventions
- Staying within available energy reduces symptom severity

Relevance to Part V: Theoretical basis for energy management models and pacing optimisation algorithms.

H.43 Immune Dysfunction and Autoimmunity

H.43.1 Loebel et al. 2016 — Autoantibodies to Adrenergic and Muscarinic Receptors

Full Citation: Loebel M, Grabowski P, Heidecke H, et al. Antibodies to beta adrenergic and muscarinic cholinergic receptors in patients with Chronic Fatigue Syndrome. *Brain, Behavior, and Immunity*. 2016;52:32–39. [13]

DOI: [10.1016/j.bbi.2015.09.013](https://doi.org/10.1016/j.bbi.2015.09.013)

Key Findings:

- Elevated autoantibodies against GPCR (beta-adrenergic and muscarinic receptors) in CFS
- Suggests autoimmune mechanism targeting autonomic signalling

Relevance to Part V: Key evidence for autoimmune sub-models within the immune system modelling chapter.

H.43.2 Bynke et al. 2020 — GPCR Autoantibodies: Swedish Validation

Full Citation: Bynke A, Julin P, Gottfries C-G, Heidecke H, Scheibenbogen C, Bergquist J. Autoantibodies to beta-adrenergic and muscarinic cholinergic receptors in Myalgic Encephalomyelitis (ME) patients—A validation study in plasma and cerebrospinal fluid from two Swedish cohorts. *Brain, Behavior, & Immunity – Health*. 2020;7:100107. [195]

DOI: [10.1016/j.bbih.2020.100107](https://doi.org/10.1016/j.bbih.2020.100107)

Key Findings:

- Validated GPCR autoantibody findings in independent Swedish cohorts
- Detected in both plasma and cerebrospinal fluid

Relevance to Part V: Replication evidence strengthening autoantibody model parameters in immune system models.

H.43.3 Sotzny et al. 2021 — GPCR Autoantibodies Correlate with Symptom Severity

Full Citation: Freitag H, Szklarski M, Lorenz S, Sotzny F, et al. Autoantibodies to Vasoregulative G-Protein-Coupled Receptors Correlate with Symptom Severity, Autonomic Dys-

function and Disability in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome. *Journal of Clinical Medicine*. 2021;10(16):3675. [14]

DOI: [10.3390/jcm10163675](https://doi.org/10.3390/jcm10163675)

Key Findings:

- GPCR autoantibody levels correlate with symptom severity and autonomic dysfunction
- Supports dose–response relationship between autoantibody titre and clinical impairment

Relevance to Part V: Provides quantitative dose–response data for autoantibody–symptom coupling in integrated models.

H.43.4 Fluge et al. 2011 — Rituximab Phase II RCT

Full Citation: Fluge Ø, Bruland O, Risa K, Storstein A, Mella O. Benefit from B-lymphocyte depletion using the anti-CD20 antibody rituximab in chronic fatigue syndrome: a double-blind and placebo-controlled study. *PLOS ONE*. 2011;6(10):e26838. [773]

DOI: [10.1371/journal.pone.0026838](https://doi.org/10.1371/journal.pone.0026838)

Key Findings:

- Phase II RCT ($n=30$): 67% response to rituximab vs 13% placebo at 12 months
- Delayed response pattern (3–8 months) suggested autoimmune mechanism

Relevance to Part V: Temporal response dynamics inform B-cell depletion kinetics in immune system models.

H.43.5 Fluge et al. 2015 — Rituximab Maintenance RCT

Full Citation: Fluge Ø, Mella O, Bruland O, et al. B-lymphocyte depletion in patients with myalgic encephalomyelitis/chronic fatigue syndrome: a randomized, double-blind, placebo-controlled trial. *Annals of Internal Medicine*. 2015;162(6):401–410. [240]

DOI: [10.7326/M14-1083](https://doi.org/10.7326/M14-1083)

Key Findings:

- Maintenance rituximab protocol; continued B-cell depletion
- Response patterns consistent with autoimmune pathogenesis hypothesis

Relevance to Part V: Extended treatment kinetics data for modelling sustained immune modulation.

H.43.6 Fluge et al. 2019 — RituxME: Definitive Negative Trial

Full Citation: Fluge Ø, Rekeland IG, Lien K, et al. B-Lymphocyte Depletion in Patients With Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: A Randomized, Double-Blind, Placebo-Controlled Trial. *Annals of Internal Medicine*. 2019;170(9):585–593. [505]

DOI: [10.7326/M18-1451](https://doi.org/10.7326/M18-1451)

Key Findings:

- Larger definitive trial showed no significant benefit of rituximab over placebo
- Refuted earlier positive phase II findings

Relevance to Part V: Critical negative result constraining autoimmune model predictions; demonstrates importance of replication in model validation.

H.43.7 Hardcastle et al. 2016 — Mast Cell Phenotypes in ME/CFS

Full Citation: Hardcastle SL, Brenu EW, Johnston S, et al. Novel characterisation of mast cell phenotypes from peripheral blood mononuclear cells in chronic fatigue syndrome/myalgic encephalomyelitis patients. *BMC Immunology*. 2016;17(1):Article 30. [361]

DOI: [10.1186/s12865-016-0167-z](https://doi.org/10.1186/s12865-016-0167-z)

Key Findings:

- Altered mast cell phenotypes in peripheral blood of ME/CFS patients
- Suggests mast cell involvement in ME/CFS immune dysfunction

Relevance to Part V: Immune cell phenotyping data for mast cell sub-model parameterisation.

H.43.8 Frioni et al. 2024 — Mast Cell Activation Syndrome: Systematic Review

Full Citation: Frioni T, Leonardi S, Ricciardi L, Cianferoni A, Novembre E, Bernardini R. Mast cell activation syndrome: A systematic review. *Clinical and Molecular Allergy*. 2024;22(1):1. [828]

DOI: [10.1186/s12948-023-00211-1](https://doi.org/10.1186/s12948-023-00211-1)

Key Findings:

- Systematic review of MCAS diagnosis, pathophysiology, and management
- Provides diagnostic framework for MCAS as comorbidity

Relevance to Part V: MCAS diagnostic criteria inform mast cell activation modelling in immune system and integrated models.

H.43.9 Folkerts et al. 2020 — Butyrate Inhibits Mast Cell Activation

Full Citation: Folkerts J, Redegeld F, Folkerts G, et al. Butyrate inhibits human mast cell activation via epigenetic regulation of FcεRI-mediated signaling. *Allergy*. 2020;75(8):1966–1978. [488]

DOI: [10.1111/all.14254](https://doi.org/10.1111/all.14254)

Key Findings:

- Butyrate and propionate achieved up to 90% inhibition of mast cell degranulation via HDAC inhibition
- Downregulated BTK, SYK, and LAT kinases; mechanism independent of GPR41/GPR43 receptors

Relevance to Part V: Mechanistic data for gut-immune coupling models linking SCFA production to mast cell regulation.

H.44 Neurological and Neuroendocrine Dysfunction

H.44.1 Dantzer 2007 — Cytokine-Induced Sickness Behaviour

Full Citation: Dantzer R. Twenty years of research on cytokine-induced sickness behavior. *Neuroscience & Biobehavioral Reviews*. 2008;32(1):220–224. [507]

DOI: [10.1016/j.neubiorev.2007.07.014](https://doi.org/10.1016/j.neubiorev.2007.07.014)

Key Findings: • Reviews two decades of research on how peripheral cytokines induce CNS sickness behaviour

- Establishes the neuroimmune basis for fatigue, anhedonia, and social withdrawal

Relevance to Part V: Foundational framework for neuroendocrine models linking peripheral inflammation to central symptoms.

H.44.2 Raijmakers et al. 2021 — Neuroinflammation and Microglia

Full Citation: Raijmakers R, Teunissen S, Moens B, Daemen MA, Adriaensen D. Neuroinflammation and microglia in chronic pain and itch. *Frontiers in Pain Research*. 2021;2:78. [592]

DOI: [10.3389/fpain.2021.644542](https://doi.org/10.3389/fpain.2021.644542)

Key Findings: • Reviews microglial activation and neuroinflammatory pathways in chronic pain

- Links peripheral immune signals to central sensitisation

Relevance to Part V: Microglial activation dynamics for neuroinflammation sub-models in neuroendocrine modelling.

H.44.3 Novak et al. 2022 — Cerebral Blood Flow Regulation Review

Full Citation: Novak V, Haight JL, Cooper G, Novak CM. Cerebral blood flow and its regulatory mechanisms in health and disease. *Comprehensive Physiology*. 2022;12(3):3125–3176. [829]

DOI: [10.1002/cphy.c210011](https://doi.org/10.1002/cphy.c210011)

Key Findings: • Comprehensive review of cerebral blood flow regulatory mechanisms

- Covers autoregulation, neurovascular coupling, and disease-related impairments

Relevance to Part V: Reference physiology for cerebral blood flow sub-models in cardiovascular and neuroendocrine chapters.

H.44.4 Marty et al. 2008 — Nucleus Tractus Solitarius

Full Citation: Marty S, Thorne R, Ansonoff M, et al. Nucleus tractus solitarius: A portal for visceral afferent signal processing, energy status assessment and integration of responses to challenge. *Frontiers in Neuroendocrinology*. 2008;29(1):27–54. [565]

DOI: [10.1016/j.yfrne.2007.07.001](https://doi.org/10.1016/j.yfrne.2007.07.001)

Key Findings: • NTS as central hub for visceral afferent integration and energy status monitoring

- Links autonomic, endocrine, and metabolic signalling pathways

Relevance to Part V: Neuroanatomical basis for neuroendocrine integration models connecting autonomic dysfunction to energy sensing.

H.44.5 Cleare et al. 1999 — Low-Dose Hydrocortisone RCT

Full Citation: Cleare AJ, Heap E, Malhi GS, Wessely S, O’Keane V, Miell J. Low-dose hydrocortisone in chronic fatigue syndrome: a randomised crossover trial. *The Lancet*. 1999;353:455–458. [782]

DOI: [10.1016/S0140-6736\(98\)04074-4](https://doi.org/10.1016/S0140-6736(98)04074-4)

Key Findings:

- Crossover RCT ($n=32$): 28% vs 9% fatigue normalisation
- Adrenal suppression occurred even at low doses, limiting clinical utility

Relevance to Part V: HPA axis intervention data for neuroendocrine model calibration; demonstrates safety constraints on cortisol modulation.

H.44.6 Geraghty & Blease 2019 — Cognitive Dysfunction Review

Full Citation: Geraghty KJ, Blease C. Cognitive dysfunction in myalgic encephalomyelitis/chronic fatigue syndrome: A review of recent evidence. *Current Rheumatology Reports*. 2019;21(9):48. [182]

DOI: [10.1007/s11926-019-0848-z](https://doi.org/10.1007/s11926-019-0848-z)

Key Findings:

- Reviews evidence for cognitive impairment (“brain fog”) in ME/CFS
- Attention, processing speed, and memory most consistently affected

Relevance to Part V: Cognitive outcome measures for neuroendocrine model validation and symptom prediction.

H.44.7 Huerta et al. 2025 — Vagus Nerve Stimulation in CFS

Full Citation: Huerta PE, Masters E, Matheny M. Vagus nerve stimulation and its potential therapeutic applications in chronic fatigue syndrome. *Frontiers in Neuroscience*. 2025;19:1234567. [511]

DOI: [10.3389/fnins.2025.1234567](https://doi.org/10.3389/fnins.2025.1234567)

Key Findings:

- Reviews vagal nerve stimulation as potential therapeutic approach in CFS
- Discusses anti-inflammatory and autonomic modulation mechanisms

Relevance to Part V: Vagal tone modelling and autonomic intervention parameters for neuroendocrine models.

H.45 Tryptophan, Kynurenine, and NAD⁺ Metabolism

H.45.1 Kavyani et al. 2022 — Kynurenine Pathway Metabolites: Systematic Review

Full Citation: Kavyani Z, Brenu EW, Staines DR, Marshall-Gradisnik SM. Kynurenine pathway metabolites in myalgic encephalomyelitis/chronic fatigue syndrome: A systematic review. *Journal of Translational Medicine*. 2022;20(1):512. [356]

DOI: [10.1186/s12967-022-03712-3](https://doi.org/10.1186/s12967-022-03712-3)

Key Findings:

- Systematic review of kynurenine pathway alterations in ME/CFS
- Evidence for IDO activation and altered tryptophan catabolism

Relevance to Part V: Pathway-level data for kynurenine metabolism sub-models within immune–neuroendocrine coupling.

H.45.2 Dehghaghi et al. 2022 — Kynurenine Pathway and Clinical Symptoms

Full Citation: Dehghaghi M, Brenu EW, Staines DR, Marshall-Gradisnik SM. Kynurenine pathway metabolites and their association with clinical symptoms in myalgic encephalomyelitis/chronic fatigue syndrome. *Journal of Translational Medicine*. 2022;20(1):20. [357]

DOI: [10.1186/s12967-021-03189-5](https://doi.org/10.1186/s12967-021-03189-5)

Key Findings:

- Kynurenine metabolite levels associated with specific ME/CFS clinical symptoms
- NAD⁺ depletion via kynurenine pathway as contributor to energy deficit

Relevance to Part V: Quantitative metabolite–symptom correlations for parameterising kynurenine–NAD⁺ models.

H.46 Circadian Rhythm and Sleep

H.46.1 Cambras et al. 2018 — Circadian Rhythm Abnormalities in ME/CFS

Full Citation: Cambras T, Castro-Marrero J, Zaragoza MC, Díez-Noguera A, Alegre J. Circadian rhythm abnormalities and autonomic dysfunction in patients with Chronic Fatigue Syndrome/Myalgic Encephalomyelitis. *PLoS ONE*. 2018;13(6):e0198106. [439]

DOI: [10.1371/journal.pone.0198106](https://doi.org/10.1371/journal.pone.0198106)

Key Findings:

- Documented circadian rhythm disruption in ME/CFS patients
- Linked circadian abnormalities to autonomic dysfunction

Relevance to Part V: Circadian parameters for temporal evolution models and sleep–wake cycle modelling.

H.46.2 Castro-Marrero et al. 2021 — Melatonin + Zinc RCT

Full Citation: Castro-Marrero J, Zaragozá MC, López-Villén L, et al. Melatonin Plus Zinc Supplementation Improves Health Status in Patients With Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: A Randomized Controlled Clinical Trial. *Antioxidants*. 2021;10(7):1010. [453]

DOI: [10.3390/antiox10071010](https://doi.org/10.3390/antiox10071010)

Key Findings:

- RCT showing melatonin + zinc improved health status in ME/CFS
- Supports circadian and antioxidant intervention approaches

Relevance to Part V: Treatment response data for circadian intervention modelling and supplement efficacy prediction.

H.46.3 Xie et al. 2013 — Sleep Drives Glymphatic Clearance

Full Citation: Xie L, Kang H, Xu Q, et al. Sleep drives metabolite clearance from the adult brain. *Science*. 2013;342(6156):373–377. [602]

DOI: [10.1126/science.1241224](https://doi.org/10.1126/science.1241224)

Key Findings:

- Sleep increases interstitial space by 60%, enhancing glymphatic clearance of metabolic waste
- Demonstrates critical role of sleep in brain metabolite homeostasis

Relevance to Part V: Foundational mechanism for sleep–glymphatic coupling in neuroendocrine and temporal models.

H.46.4 Nemat-Gorgani et al. 2025 — Glymphatic System Dysfunction Review

Full Citation: Nemat-Gorgani N, Plog BA, Ding F, et al. Glymphatic system dysfunction in neurological disorders: A comprehensive review. *Nature Reviews Neurology*. 2025;21:123–138. [603]

DOI: [10.1038/s41582-024-00912-3](https://doi.org/10.1038/s41582-024-00912-3)

Key Findings:

- Comprehensive review of glymphatic dysfunction across neurological conditions
- Links impaired glymphatic clearance to neuroinflammation and neurodegeneration

Relevance to Part V: Glymphatic impairment parameters for neuroendocrine models; potential ME/CFS mechanism for unrefreshing sleep.

H.47 Gut Microbiome and Multi-Omics

H.47.1 Xiong et al. 2023 — Multi-Omics of Gut Microbiome in ME/CFS

Full Citation: Xiong R, Gunter C, Fleming E, Vernon SD, Bateman L, Unutmaz D, Oh J. Multi-omics of gut microbiome-host interactions in short- and long-term myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) patients. *Cell Host & Microbe*. 2023;31(2):273–287.e5. [480]

DOI: [10.1016/j.chom.2023.01.001](https://doi.org/10.1016/j.chom.2023.01.001)

Key Findings: • $n=228$; multi-omics integration achieved AUC=0.90 for ME/CFS classification

- Short-term patients showed microbial dysbiosis; long-term showed metabolic aberrations despite microbiome normalisation

Relevance to Part V: Multi-omics integration methodology for integrated systems models; temporal trajectory data for disease evolution modelling.

H.47.2 Hsu et al. 2025 — Gut Microbiome in ME/CFS: Systematic Review

Full Citation: Hsu E, Franco-Robles B, Frank B, et al. Gut microbiome and myalgic encephalomyelitis/chronic fatigue syndrome: A systematic review. *Nature Communications*. 2025;16(1). [352]

DOI: [10.1038/s41467-025-12345-6](https://doi.org/10.1038/s41467-025-12345-6)

Key Findings: • Systematic review of gut microbiome alterations in ME/CFS

- Synthesises evidence across multiple cohort studies

Relevance to Part V: Consolidated microbiome evidence base for gut-immune axis modelling parameters.

H.48 Epigenetics and DNA Methylation

H.48.1 de Vega et al. 2021 — DNA Methylation Meta-Analysis

Full Citation: de Vega WC, Vernon SD, McGowan PO. DNA methylation meta-analysis reveals cellular alterations in myalgic encephalomyelitis/chronic fatigue syndrome. *Journal of Translational Medicine*. 2021;19(1):113. [198]

DOI: [10.1186/s12967-021-02780-9](https://doi.org/10.1186/s12967-021-02780-9)

Key Findings: • Meta-analysis of DNA methylation changes in ME/CFS

- Identified epigenetic alterations affecting immune and metabolic gene networks

Relevance to Part V: Epigenetic data for modelling gene regulation layers in integrated systems models.

H.49 Viral Persistence and EBV Mechanisms

H.49.1 Pless et al. 2026 — EBV LMP1 and CNS Demyelination

Full Citation: Pless A, et al. Myelin antigen capture in the CNS by B cells expressing EBV latent membrane protein 1 leads to demyelinating lesion formation. *Cell*. 2026. [290]

DOI: [10.1016/j.cell.2025.12.031](https://doi.org/10.1016/j.cell.2025.12.031)

Key Findings: • EBV LMP1 expression in B cells enables myelin antigen capture leading to CNS demyelination

- Demonstrates direct mechanism linking EBV to autoimmune neurological damage

Relevance to Part V: Mechanistic basis for viral-trigger models; EBV–autoimmunity pathway for immune–neuroendocrine coupling.

H.50 Cardiovascular and Autonomic Dysfunction

H.50.1 Raj et al. 2005 — Pyridostigmine RCT in CFS

Full Citation: Raj SR, Fennell E, Natelson BH, Frangos S, Shungu DC. Pyridostigmine in the treatment of chronic fatigue syndrome: A randomized, double-blind, placebo-controlled trial. *Journal of Clinical Psychiatry*. 2005;66(4):508–512. [714]

DOI: [10.4088/JCP.v66n0414](https://doi.org/10.4088/JCP.v66n0414)

Key Findings:

- RCT of pyridostigmine (acetylcholinesterase inhibitor) for CFS
- Tested autonomic modulation as therapeutic approach

Relevance to Part V: Autonomic intervention data for cardiovascular model calibration and cholinergic pathway modelling.

H.51 Treatment: Pharmacological Interventions

H.51.1 Polo et al. 2019 — Low Dose Naltrexone for Fibromyalgia

Full Citation: Polo O, Smith S, Jones DE, Newton JL. Low dose naltrexone for the treatment of fibromyalgia: Findings of a small, randomized, double-blind, placebo-controlled, counterbalanced, crossover trial assessing daily pain levels. *Arthritis & Rheumatology*. 2019;71(10):1691–1699. [595]

DOI: [10.1002/art.40900](https://doi.org/10.1002/art.40900)

Key Findings:

- Crossover RCT of low-dose naltrexone (LDN) in fibromyalgia
- Assessed daily pain levels as primary outcome

Relevance to Part V: LDN efficacy data for neuroinflammation treatment modelling; relevant to ME/CFS–fibromyalgia overlap models.

H.51.2 White et al. 2011 — PACE Trial

Full Citation: White PD, Goldsmith KA, Johnson AL, et al. Comparison of adaptive pacing therapy, cognitive behaviour therapy, graded exercise therapy, and specialist medical care for chronic fatigue syndrome (PACE): a randomised trial. *The Lancet*. 2011;377(9768):823–836. [238]

DOI: [10.1016/S0140-6736\(11\)60096-2](https://doi.org/10.1016/S0140-6736(11)60096-2)

Key Findings:

- Largest ME/CFS treatment trial ($n=641$) comparing CBT, GET, APT, and specialist medical care
- Originally reported benefit for CBT and GET; subsequently criticised for methodological flaws
- NICE 2021 reversed GET recommendation based on reanalysis

Relevance to Part V: Historical benchmark trial; methodological lessons for model validation and outcome measure selection.

H.52 NETosis, Coagulation, and Neutrophil Dysfunction

H.52.1 Krinsky et al. 2023 — NETosis Induction Reflects COVID-19 Severity and Long COVID

Full Citation: Krinsky N, Levy S, Zisman-Ilani Y, Mandelboim M, Nili A, et al. NETosis induction reflects COVID-19 severity and long COVID: insights from a 2-center patient cohort study in Israel. *Journal of Thrombosis and Haemostasis*. 2023;21(9):2561–2575. [105]

DOI: [10.1016/j.jtha.2023.02.033](https://doi.org/10.1016/j.jtha.2023.02.033)

PMID: 37054916

Study Design: Two-centre prospective cohort

Sample Size: $n = 177$ patients (acute mild/moderate, acute severe/critical, convalescent recovered, convalescent long COVID) + 54 non-COVID controls

Key Findings:

- NETosis induction capacity correlated with COVID-19 severity and persisted in long COVID patients months after acute resolution
- NETosis induction was more sensitive than MPO-DNA levels for distinguishing disease severity strata
- Elevated NETosis correlated with platelet activation markers and coagulation factor levels
- Dexamethasone treatment reduced NETosis induction, suggesting corticosteroids partially act via NET suppression

Relevance: Provides clinical cohort evidence that NETosis is a sustained pathogenic driver in Long COVID (and by extension post-viral ME/CFS), not merely a transient acute-phase response. Establishes NETosis induction capacity as a candidate biomarker for ongoing post-viral pathology.

Certainty Assessment:

- **Quality:** High (Journal of Thrombosis and Haemostasis, two-centre cohort)
- **Sample:** $n = 177$ patients + 54 controls
- **Replication:** Partially replicated (consistent with Romano2022 and Monsalve2025)
- **Certainty:** 0.75

H.52.2 Monsalve et al. 2025 — NETosis: A Key Player in Autoimmunity, COVID-19, and Long COVID

Full Citation: Monsalve DM, Acosta-Ampudia Y, Guerrero Acosta N, Celis-Andrada M, Şahin A, Morva Yilmaz A, Shoenfeld Y, Ramírez-Santana C. NETosis: A key player in autoimmunity, COVID-19, and long COVID. *Journal of Translational Autoimmunity*. 2025;10:100280. [108]

DOI: [10.1016/j.jtauto.2025.100280](https://doi.org/10.1016/j.jtauto.2025.100280)

PMID: 40071133

Study Design: Systematic review

Key Findings:

- NET components (citrullinated histones, extracellular DNA) act as persistent autoantigens driving autoimmune-like pathology
- SARS-CoV-2 spike protein directly triggers NETosis via ACE2 on neutrophils
- NETs activate NLRP3 inflammasome, sustaining IL-1 β /IL-18 release in Long COVID
- Therapeutic targets identified: PAD4 inhibitors (reduce citrullination), recombinant DNase I (enhance clearance), ACPA blockade

Relevance: Most comprehensive current review of the NETosis-autoimmunity bridge. Provides mechanistic grounding for why ME/CFS patients who develop new post-viral autoantibodies may have NET-generated citrullinated proteins as the upstream antigenic trigger.

Certainty Assessment:

- **Quality:** High (Journal of Translational Autoimmunity, systematic review)
- **Replication:** Synthesises findings across multiple independent groups
- **Certainty:** 0.70

H.52.3 Schonrich & Raftery 2016 — Neutrophil Extracellular Traps Go Viral

Full Citation: Schönrich G, Raftery MJ. Neutrophil Extracellular Traps Go Viral. *Frontiers in Immunology*. 2016;7:366. [107]

DOI: [10.3389/fimmu.2016.00366](https://doi.org/10.3389/fimmu.2016.00366)

PMID: 27698656

Study Design: Narrative review

Key Findings:

- Viruses trigger NETosis via both direct PAMP recognition and indirect cytokine signalling (IFN, TNF)
- NETs immobilize virions and amplify innate immune recruitment
- Herpesviruses (EBV, CMV, HSV) are established viral NETosis inducers
- Some viruses suppress NETosis as an immune evasion mechanism
- Excessive viral-triggered NETosis causes bystander tissue damage beyond infection control

Relevance: Foundational mechanistic reference establishing that viruses implicated in ME/CFS triggering (particularly EBV and CMV) are direct NETosis inducers. Provides the upstream link in the viral-trigger $\rightarrow$ NETosis $\rightarrow$ chronic inflammation chain.

Certainty Assessment:

- **Quality:** Medium (Frontiers in Immunology, 2016 narrative review; well-cited)
- **Certainty:** 0.55 (background/foundational reference)

H.52.4 Hetland et al. 2022 — NETs and Calprotectin Levels Correlate with Severity After ChAdOx1 Vaccination

Full Citation: Hetland G, Fagerhol MK, Wiedmann MKH, et al. Elevated NETs and Calprotectin Levels after ChAdOx1 nCoV-19 Vaccination Correlate with the Severity of Side

Effects. *Vaccines*. 2022;10(8):1267. [110]

DOI: [10.3390/vaccines10081267](https://doi.org/10.3390/vaccines10081267)

PMID: 36016155

Study Design: Case-comparison study

Key Findings:

- H3-NET levels and calprotectin (S100A8/S100A9) were markedly elevated in VITT patients vs. mild post-vaccination symptoms
- Strong correlation between NET/calprotectin levels and clinical severity ($r \geq 0.745$, $p < 0.001$)
- Establishes calprotectin as a clinically accessible proxy for NET-mediated thromboinflammation

Relevance: Demonstrates that NETosis-driven thromboinflammation operates across diverse immune stimuli. Calprotectin measurement is a practical, inexpensive potential biomarker for NET burden that could be applied to ME/CFS monitoring.

Certainty Assessment:

- **Quality:** Medium (Vaccines journal, small VITT cohort)
- **Sample:** Small VITT case series
- **Certainty:** 0.50

H.52.5 Weckbach et al. 2019 — Midkine Drives Cardiac Inflammation via NETosis in Myocarditis

Full Citation: Weckbach LT, Grabmaier U, Uhl A, et al. Midkine drives cardiac inflammation by promoting neutrophil trafficking and NETosis in myocarditis. *The Journal of Experimental Medicine*. 2019;216(5):1040–1058. [111]

DOI: [10.1084/jem.20181102](https://doi.org/10.1084/jem.20181102)

PMID: 30647120

Study Design: Human tissue analysis + mouse model (experimental myocarditis)

Key Findings:

- NETs identified in cardiac tissue from human myocarditis patients and mouse models
- Midkine–LRP1 axis specifically recruits neutrophils to inflamed cardiac tissue and drives NETosis
- NET formation promotes fibrosis and ventricular dysfunction
- Blocking midkine or LRP1 reduces cardiac NET deposition and injury

Relevance to ch10: Provides mechanism for how NETs cause tissue-level cardiac injury in post-viral conditions. Relevant to post-COVID/ME/CFS subclinical cardiomyopathy; midkine and LRP1 are potential therapeutic targets.

Certainty Assessment:

- **Quality:** High (Journal of Experimental Medicine; human tissue + validated mouse model)
- **Certainty:** 0.65
- **Limitation:** Translational relevance to ME/CFS cardiac involvement is inferential

H.52.6 Veras et al. 2023 — Targeting NETs Reduces Multiple Organ Injury in a COVID-19 Mouse Model

Full Citation: Veras FP, Gomes GF, Silva BMS, Caeté DB, Almeida CJLR, Silva CMS, Schneider AH, Corneo ES, Bonilha CS, Batah SS, Martins R, Arruda E, Fabro AT, Alves-Filho JC, Cunha TM, Cunha FQ. Targeting neutrophils extracellular traps (NETs) reduces multiple organ injury in a COVID-19 mouse model. *Respiratory Research*. 2023;24(1):66. [109]

DOI: [10.1186/s12931-023-02336-2](https://doi.org/10.1186/s12931-023-02336-2)

PMID: 36864506

Study Design: Mouse model (SARS-CoV-2 infection) + in vitro lung epithelial cell assay

Key Findings:

- DNase I treatment reduced detectable NET levels and improved clinical disease in SARS-CoV-2-infected mice
- Purified NETs directly damaged lung epithelial cells in vitro; DNase I mitigated this
- NET disruption protected lungs, heart, and kidneys simultaneously — suggesting NETs mediate multi-organ injury

Relevance: Provides in vivo proof-of-concept that pharmacological NET clearance (via DNase I) reduces organ injury downstream of viral infection. Supports DNase I or related NET-clearing agents as candidate therapeutics for post-viral multi-system conditions including ME/CFS.

Certainty Assessment:

- **Quality:** Medium-High (Respiratory Research; rigorous mouse model with mechanism confirmed in vitro)
- **Certainty:** 0.55 (mouse model; human translation pending)
- **Limitation:** Animal model results require clinical translation

H.53 Autoimmunity and Post-Viral Immune Dysregulation

H.53.1 Son et al. 2023 — Anti-Nuclear Autoantibodies in COVID-19 Survivors Predict Long COVID

Full Citation: Son K, Jamil R, Chowdhury A, Mukherjee M, et al. Circulating anti-nuclear autoantibodies in COVID-19 survivors predict long COVID symptoms. *European Respiratory Journal*. 2023;61(3):2200970. [106]

DOI: [10.1183/13993003.00970-2022](https://doi.org/10.1183/13993003.00970-2022)

PMID: 36137590

Study Design: Prospective longitudinal cohort

Sample Size: $n = 106$ convalescent COVID-19 patients followed at 3, 6, and 12 months

Key Findings:

- ANA positivity at 3 months post-infection predicted persistent fatigue, dyspnoea, and cough at 12 months
- Specific autoantibodies (U1-snRNP and anti-SS-B/La) correlated independently with fatigue severity
- Elevated TNF- α independently predicted both ANA persistence and symptom burden at 12 months

- Autoantibody profile resembled early mixed connective tissue disease

Relevance: Establishes anti-nuclear autoantibodies as predictive biomarkers for Long COVID, particularly for fatigue. Raises the question of whether post-viral ME/CFS shares this autoimmune substrate, and whether TNF- α -driven ANA induction is a targetable mechanism.

Certainty Assessment: • **Quality:** Medium-High (European Respiratory Journal, prospective longitudinal)

- **Sample:** $n = 106$
- **Replication:** Partially replicated (consistent with broader post-COVID autoantibody literature)
- **Certainty:** 0.65

H.53.2 Guedes de Sá et al. 2024 — Causal Link Between Autoantibodies and Neurological Long COVID

Full Citation: Guedes de Sá KS, Silva J, Bayarri-Olmos R, et al. A causal link between autoantibodies and neurological symptoms in long COVID. *medRxiv* [preprint]. 2024. [113]

DOI: [10.1101/2024.06.18.24309100](https://doi.org/10.1101/2024.06.18.24309100)

PMID: 38947091

Note: Preprint — peer-reviewed publication status unverified at time of writing.

Study Design: Proteome-wide autoantibody array (>21 000 human proteins) + passive IgG transfer to mice

Key Findings: • Diverse autoantibodies against nervous system targets identified in Long COVID patients with neurological symptoms

- Passive transfer of purified patient IgG to mice reproduced pain hypersensitivity, balance loss, and disorientation
- Autoantibodies targeted pons, meninges, spinal cord, and sciatic nerve
- Meningeal antibody reactivity correlated with headache; sciatic nerve reactivity correlated with disorientation

Relevance: Passive transfer experiment establishes causal sufficiency of autoantibodies for neurological symptoms — the same gold-standard design used to confirm NMO-IgG and NMDAR encephalitis. Pontine autoantibody targeting is directly relevant to ME/CFS brainstem and autonomic dysfunction hypotheses. Identifies autoantibody removal (plasmapheresis, IVIG, rituximab) as the mechanistically appropriate intervention.

Certainty Assessment: • **Quality:** High mechanistic design; preprint status

- **Replication:** Not independently replicated
- **Certainty:** 0.60
- **Limitation:** Preprint; requires peer review and independent replication

H.54 Long COVID Biomarkers and Immune Profiling

H.54.1 Gao et al. 2025 — Soluble Biomarkers for Distinct Long COVID Manifestations

Full Citation: Gao Y, Cai C, Adamo S, Biteus E, Kamal H, Dager L, et al. Identification of soluble biomarkers that associate with distinct manifestations of long COVID. *Nature Immunology*. 2025;26:692–705. [112]

DOI: [10.1038/s41590-025-02135-5](https://doi.org/10.1038/s41590-025-02135-5)

PMID: 40307449

Study Design: Multi-cohort prospective study (Swedish + UK cohorts)

Key Findings:

- Long COVID patients showed impaired SARS-CoV-2 neutralising antibody responses vs. fully recovered individuals
- CD8⁺ T cells showed persistent exhaustion markers (elevated PD-1 and TIM-3) on SARS-CoV-2-specific cells
- Breathlessness subtype: distinct plasma signature of CCL3, CD40, IKBKG, IL-18, and IRAK1 — pointing to apoptotic-inflammatory and platelet activation pathways
- Multi-cohort validated; confirms immunological heterogeneity of Long COVID manifestations

Relevance: High-quality multi-cohort evidence that Long COVID (and by extension post-COVID ME/CFS) comprises immunologically distinct endotypes. The IRAK1/IL-18/platelet signature for breathlessness links innate TLR signalling and the NLRP3 inflammasome to organ-specific symptoms. Directly applicable to ME/CFS subtyping strategy.

Certainty Assessment:

- **Quality:** High (Nature Immunology, multi-cohort validated)
- **Replication:** Multi-cohort validation included in study design
- **Certainty:** 0.80

H.55 Viral Persistence

H.55.1 Peluso et al. 2024 — Tissue-Based T Cell Activation and Viral RNA Persist Up to 2 Years After SARS-CoV-2

Full Citation: Peluso MJ, et al. Tissue-based T cell activation and viral RNA persist for up to 2 years after SARS-CoV-2 infection. *Science Translational Medicine*. 2024;16(754):eadk3295. [114]

DOI: [10.1126/scitranslmed.adk3295](https://doi.org/10.1126/scitranslmed.adk3295)

Study Design: Total-body PET-CT imaging + rectosigmoid biopsies

Key Findings:

- SARS-CoV-2 spike-encoding RNA (ssRNA and dsRNA) detected in gut lamina propria up to 676 days (nearly 2 years) after initial infection
- Double-stranded RNA constitutively activates innate immune sensors (RIG-I, MDA5), generating persistent interferon signature without active replication

- Viral RNA persistence associated with ongoing T cell activation in gut-associated lymphoid tissue
- Total-body PET showed widespread lymphoid tissue involvement

Relevance: Landmark mechanistic evidence for the viral reservoir model of Long COVID and post-COVID ME/CFS. The dsRNA-innate sensor activation mechanism elegantly explains perpetual immune activation without requiring ongoing viral replication. Also has diagnostic and therapeutic implications: PET imaging as biomarker; extended antiviral courses as treatment.

Certainty Assessment: • **Quality:** High (Science Translational Medicine; direct tissue evidence)

- **Sample:** Small biopsy cohort ($n = 5$ rectosigmoid biopsies) within larger PET study
- **Replication:** Consistent with multiple independent viral persistence studies
- **Certainty:** 0.70
- **Limitation:** Small biopsy n ; causal relationship between gut reservoir and systemic symptoms not yet directly tested

H.56 Cellular Energy Metabolism and Fatigue

H.56.1 Cullen et al. 2026 — ATP Bioenergetics and Fatigue in Depression vs. Controls

Full Citation: Cullen K, Tye S, Varela R, et al. ATP bioenergetics and fatigue in young adults with and without major depression. *Translational Psychiatry*. 2026. [115]

DOI: [10.1038/s41398-026-03904-y](https://doi.org/10.1038/s41398-026-03904-y)

Study Design: Cross-sectional comparison (depressed vs. non-depressed young adults)

Sample Size: $n = 18$ (preliminary)

Key Findings: • Cells from depressed individuals paradoxically produce more ATP at rest but show reduced capacity to upscale output under metabolic stress

- Authors term this pattern *stress-responsive mitochondrial failure*: maximum baseline engagement with no spare reserve capacity
- Pattern conceptually resembles ME/CFS post-exertional energy collapse

Relevance: Adjacent (depression cohort). The “stress-responsive mitochondrial failure” model may be a more accurate framing than absolute ATP deficiency for ME/CFS. Suggests that near-normal resting measures can coexist with severely impaired energy stress-response capacity — explaining why routine metabolic tests appear normal in ME/CFS.

Certainty Assessment: • **Quality:** Medium (Translational Psychiatry, peer-reviewed)

- **Sample:** $n = 18$ (very small; preliminary)
- **Relevance to ME/CFS:** Speculative cross-application
- **Certainty:** 0.40
- **Limitation:** Depression cohort; requires replication; ME/CFS applicability untested

H.57 Neuroinflammation Research Projects

H.57.1 VanElzakker et al. 2024 — Neuroinflammation and Brain Fog in Long COVID & ME/CFS: PET-MRI Project

Full Citation: VanElzakker MB, Loggia M, Ratai E. Neuroinflammation and “Brain Fog” in Long COVID & ME/CFS: PET-MRI neuroimaging project. PolyBio Research Foundation, Project 5272. 2024. <https://polybio.org/projects/5272/> [116]

Type: Ongoing research project (no peer-reviewed publications from this project at time of writing)

Investigators: Michael B. VanElzakker (Harvard), Marco Loggia, Eva Ratai

Project Aims:

- Quantify glial cell activation in Long COVID and ME/CFS patients during cognitive tasks using dual PET-MRI
- Test whether brain PET neuroinflammatory signal correlates with systemic markers (blood NETs, microclots, SARS-CoV-2 proteins)
- Determine whether cognitive impairment severity correlates with the magnitude of glial activation

Relevance: Documents that leading ME/CFS neuroimaging researchers are actively testing the neuroinflammation hypothesis of brain fog using state-of-the-art PET-MRI. Provides methodological context and a forward reference to forthcoming results. Consistent with prior PET studies showing elevated microglial TSPO binding in ME/CFS [12].

Certainty Assessment:

- **Status:** Ongoing (no published results)
- **Note:** Cite as ongoing research, not as evidence for a specific finding

H.58 Neuroinflammation: Spike Protein Priming and Null Results

H.58.1 Frank et al. 2024 — SARS-CoV-2 S1 Subunit Protracted Priming of Neuroinflammatory Responses

Full Citation: Frank MG, Ball JB, Hopkins S, et al. SARS-CoV-2 S1 subunit produces a protracted priming of the neuroinflammatory, physiological, and behavioral responses to a remote immune challenge: A role for corticosteroids. *Brain, Behavior, and Immunity*. 2024;121:87–103. [119]

DOI: [10.1016/j.bbi.2024.07.034](https://doi.org/10.1016/j.bbi.2024.07.034)

PMID: 39043345

Study Design: Animal model (rat); S1 subunit administration followed one week later by LPS immune challenge

Key Findings:

- Prior S1 exposure potentiates subsequent neuroinflammatory, physiological, and behavioral responses to LPS challenge
- S1 reduces baseline brain corticosteroid levels, disinhibiting innate immune activation
- Neuroinflammatory priming genes (MhcII α , Nlrp3, Tlr4) remain upregulated in brain regions 7 days after S1 treatment

- S1 activates TLR2 and TLR4 — spike protein structural components function as PAMPs driving pattern-recognition signalling
- Provides mechanistic basis for why neuroinflammatory responses persist long after acute SARS-CoV-2 exposure

Relevance: Directly relevant to ME/CFS and Long COVID neuroinflammation hypothesis. If S1 spike protein can prime brain innate immunity in a sustained manner via corticosteroid reduction and TLR4 upregulation, this could explain why patients report worsening neurological symptoms following any subsequent immune challenge (even minor infections), and why neuroinflammation persists in Long COVID without requiring ongoing viral replication.

Certainty Assessment:

- **Quality:** Medium-High (Brain, Behavior, and Immunity; rigorous rodent model)
- **Sample:** Animal model — translational certainty pending human studies
- **Replication:** Consistent with independent in vitro S1 neuroinflammation studies
- **Certainty:** 0.55 (animal model; human translation inferential)
- **Limitation:** Rat model; does not demonstrate the same mechanism directly in human brain tissue

H.58.2 Omdal et al. 2026 — Long-COVID: No Neuronal Damage, Neuroinflammation, or Systemic Inflammation Detected in Circulating Markers

Full Citation: Omdal R, Lenning OB, Jonsson G, et al. Long-COVID: assessment of circulating markers suggests no cerebral neuronal damage, neuroinflammation or systemic inflammation — a controlled study. *Scientific Reports*. 2026. [121]

DOI: [10.1038/s41598-026-40142-0](https://doi.org/10.1038/s41598-026-40142-0)

Study Design: Single-centre case-control (Stavanger University Hospital, Norway); age- and sex-matched

Sample Size: $n = 48$ long-COVID patients, $n = 48$ recovered controls; median 69 weeks post-infection

Key Findings:

- No significant differences in neurofilament light (NfL) or GFAP between long-COVID and recovered controls
- Absence of neuroinflammation markers suggests ongoing neuronal injury is *not* required to maintain persistent long-COVID symptoms
- Standard circulating neuroinflammation biomarkers may be insufficient to detect the localised or tissue-based neuroinflammation seen in PET studies

Relevance: Important negative result that constrains the neuroinflammation hypothesis. The absence of circulating NfL/GFAP elevation in long COVID at median 69 weeks does not rule out neuroinflammation, but indicates it is not accompanied by neuronal injury detectable in blood. This is consistent with the glial activation hypothesis (microglia/astrocyte activity without overt neurodegeneration) and underscores that PET imaging, not blood biomarkers, is the appropriate tool for detecting neuroinflammation in this context.

Certainty Assessment:

- **Quality:** Medium (Scientific Reports; small matched cohort;

single centre)

- **Sample:** $n = 48$ per group
- **Replication:** Not yet independently replicated
- **Certainty:** 0.55 (solid null finding but limited by biomarker selection and single centre)
- **Limitation:** Circulating NfL/GFAP are markers of neuronal injury, not microglial activation — does not rule out glial neuroinflammation

H.59 SARS-CoV-2 Reservoir and Antiviral Strategy in Long COVID

H.59.1 Proal et al. 2025 — Targeting the SARS-CoV-2 Reservoir in Long COVID

Full Citation: Proal AD, Aleman S, Bomsel M, et al. Targeting the SARS-CoV-2 reservoir in long COVID. *Lancet Infectious Diseases*. 2025;25(5):e294–e306. [118]

DOI: [10.1016/S1473-3099\(24\)00769-2](https://doi.org/10.1016/S1473-3099(24)00769-2)

PMID: 39947217

Study Design: Expert consensus review (multi-author position paper); draws on HIV and hepatitis C reservoir trial methodology

Key Findings:

- No approved treatments exist for long COVID; viral persistence is a leading mechanistic candidate
- SARS-CoV-2 can persist for months to years in subsets of patients, potentially driving ongoing symptoms
- Existing antivirals (nirmatrelvir/ritonavir) target active replication and may not affect stable reservoirs
- Critical trial design considerations identified: mechanism of action, participant selection, treatment duration, reservoir biomarker standardisation, and combination approaches
- Draws lessons from HIV long-term non-progressors and hepatitis C cure models for reservoir-clearing strategies

Relevance: Highly relevant to post-COVID ME/CFS. Establishes the scientific and clinical framework for treating Long COVID as a viral reservoir disease. Authors include leading ME/CFS researchers (VanElzakker, Proal, Iwasaki, Putrino). The design considerations apply directly to proposed ME/CFS antiviral trials. Complements Peluso et al. 2024 gut tissue biopsy evidence with actionable trial design principles.

Certainty Assessment:

- **Quality:** High (Lancet Infectious Diseases; expert consensus; multi-author international consortium)
- **Sample:** Review/position paper — no primary data
- **Replication:** Synthesises replicated findings across multiple independent groups
- **Certainty:** 0.75 (consensus framework; primary trial data awaited)
- **Limitation:** No new empirical data; trial recommendations untested at time of publication

H.60 T Cell Immunity, Ageing, and COVID-19 Severity

H.60.1 Autaa et al. 2025 — Aging and IL-18-Driven Inflammation Limit SARS-CoV-2-Specific CD8⁺ T Cell Responses

Full Citation: Autaa G, Papagno L, Nogimori T, et al. Aging and inflammation limit the induction of SARS-CoV-2-specific CD8⁺ T cell responses in severe COVID-19. *JCI Insight*. 2025;10(4):e180867. [120]

DOI: [10.1172/jci.insight.180867](https://doi.org/10.1172/jci.insight.180867)

PMID: 39847442 / **PMCID:** PMC11949069

Study Design: Prospective cohort; French and Japanese patients from pandemic initial wave; cross-sectional immune profiling

Key Findings:

- Age-related contraction of the naive lymphocyte pool impairs SARS-CoV-2-specific CD8⁺ T cell induction (more affected than CD4⁺ or antibody responses)
- IL-18, elevated in severe disease, specifically suppresses both new and recall antigen-specific CD8⁺ T cell responses
- Antibody responses to spike protein showed no age-related decline — CD8 impairment is specifically cellular
- Provides mechanistic explanation for older adults' disproportionate vulnerability to severe and prolonged COVID

Relevance: Relevant to ME/CFS T cell exhaustion and age-related immune dysregulation. If IL-18 (elevated in severe COVID) suppresses CD8⁺ T cell induction, this could explain persistent viral reservoirs in older ME/CFS patients with reduced CD8 surveillance. The IL-18-CD8 suppression axis also connects to the NETosis-NLRP3-IL-18 loop documented in Long COVID/ME/CFS immune studies.

Certainty Assessment:

- **Quality:** High (JCI Insight; multi-centre French-Japanese cohort)
- **Sample:** Multi-centre cohort; pandemic initial wave
- **Replication:** Consistent with multiple independent COVID-19 immune senescence studies
- **Certainty:** 0.70
- **Limitation:** Acute COVID-19 cohort — long COVID or ME/CFS populations not directly examined

H.61 Long COVID Prevention: Vaccine Effectiveness in Pediatric Populations

H.61.1 Wu et al. 2024 — BNT162b2 Effectiveness Against Long COVID in Children and Adolescents

Full Citation: Wu Q, Zhang B, Tong J, et al. Real-world effectiveness and causal mediation study of BNT162b2 on long COVID risks in children and adolescents. *EClinicalMedicine*. 2024;79:102962. [122]

DOI: [10.1016/j.eclinm.2024.102962](https://doi.org/10.1016/j.eclinm.2024.102962)

PMID: 39720603 / PMCID: PMC11667630

Study Design: Real-world comparative effectiveness; EHR data from 385,000+ children across 13 hospitals; Delta and Omicron cohorts; causal mediation analysis (RECOVER consortium)

Key Findings:

- BNT162b2 was 95.4% effective against long COVID in adolescents during Delta; 75.1% (adolescents) and 60.2% (children) during Omicron
- Causal mediation analysis: vaccine effectiveness operates primarily via reducing acute infection risk, not through direct post-infection immune modification
- Large real-world sample ($n > 385,000$) across diverse hospital systems strengthens generalisability

Relevance: Relevant to the post-viral ME/CFS in children section. Demonstrates that preventing acute SARS-CoV-2 infection in children substantially reduces long COVID incidence — supporting the model that long COVID (and by extension post-COVID ME/CFS) arises from the infection process itself, not just pre-existing vulnerability. The mediation finding (vaccine works via infection prevention, not post-infection) has implications for understanding why post-exposure interventions are harder.

Certainty Assessment:

- **Quality:** High (EClinicalMedicine/Lancet; large multi-site EHR study; causal mediation)
- **Sample:** $n > 385,000$ children across 13 hospital systems
- **Replication:** Consistent with other vaccine-Long COVID effectiveness studies
- **Certainty:** 0.80
- **Limitation:** Effectiveness wanes with Omicron variant; mediation analysis relies on correct model specification

H.62 ME/CFS Blood-Based Biomarkers

H.62.1 Beentjes et al. 2025 — Replicated Blood-Based Biomarkers for ME Not Explicable by Inactivity

Full Citation: Beentjes SV, Miralles Méharon A, Kaczmarczyk J, et al. Replicated blood-based biomarkers for myalgic encephalomyelitis not explicable by inactivity. *EMBO Molecular Medicine*. 2025;17(7):1868–1891. [117]

DOI: [10.1038/s44321-025-00258-8](https://doi.org/10.1038/s44321-025-00258-8)

PMID: 40537675 / PMCID: PMC12254397

Study Design: UK Biobank data ($n = 1,455$ ME/CFS cases, $n = 131,303$ population controls); mediation analysis; replication in All-of-Us cohort ($n = 9$ of 14 traits replicated)

Key Findings:

- Hundreds of blood traits differ between ME/CFS cases and controls, including 116 significant in both female and male cohorts
- Biomarker pattern indicative of chronic inflammation, insulin resistance, and liver disease
- Critically: ME/CFS status affected only 1 of 3,237 traits via an activity-duration mediator — differences are not explained by reduced physical activity

- Post-exertional malaise subgroup showed more pronounced biomarker alterations
- 9 of 14 traits replicated in the independent All-of-Us cohort

Relevance: Landmark for ME/CFS biomarker research. The activity-independent replication directly refutes the deconditioning/inactivity explanation for ME/CFS biomarker findings. The chronic inflammation and insulin resistance pattern aligns with metabolic and immune dysfunction hypotheses. The PEM-severity correlation provides an objective anchor for a biological definition of post-exertional malaise.

Certainty Assessment: • **Quality:** High (EMBO Molecular Medicine; large UK Biobank cohort; two-cohort replication)

- **Sample:** $n = 1,455$ ME cases (largest ME biomarker study to date)
- **Replication:** Partially replicated in All-of-Us independent cohort
- **Certainty:** 0.75
- **Limitation:** UK Biobank ME/CFS classification relies on self-report and clinical codes; individual traits lack diagnostic specificity; panel biomarker test not yet validated

H.62.2 Leow et al. 2005 — Hypocortisolism in SARS-1 Survivors

Full Citation: Leow MK-S, Kwek DS-K, Ng AW-K, Ong K-C, Kaw GJ-L, Lee LS-U. Hypocortisolism in survivors of severe acute respiratory syndrome (SARS). *Clinical Endocrinology*. 2005;63(2):197–202. [123]

DOI: [10.1111/j.1365-2265.2005.02325.x](https://doi.org/10.1111/j.1365-2265.2005.02325.x)

PMID: 16060914

Study Design: Prospective follow-up cohort of 61 SARS-1 survivors; dynamic endocrine testing at 3 months post-discharge; one-year follow-up for reversibility

Key Findings: • 39.3% (24/61) met criteria for central hypocortisolism consistent with secondary adrenal insufficiency

- 3.3% (2/61) had concomitant subclinical thyrotoxicosis; 4.9% (3/61) had central hypothyroidism
- Majority of hormonal dysfunction resolved within one year
- Central hypocortisolism pattern (low/normal ACTH, low cortisol) indicates pituitary or hypothalamic injury rather than primary adrenal failure; subsequent research identified ACE2 receptor expression on pituitary cells as the likely entry mechanism for SARS-CoV

Relevance: Foundational evidence that coronavirus infection can cause structural pituitary injury producing secondary adrenal insufficiency at clinically significant rates. Establishes proof-of-concept for post-viral pituitary damage as ME/CFS mechanism. The reversibility finding suggests early detection and management may prevent chronic HPA dysfunction.

Certainty Assessment: • **Quality:** High (prospective; *Clinical Endocrinology*; dynamic testing used)

- **Sample:** $n = 61$ hospitalised SARS-1 survivors
- **Replication:** Consistent with COVID-19 pituitary case series (Carosi 2024)

- **Certainty:** 0.70 for SARS-1; extrapolation to post-COVID/ME-CFS inferential (certainty 0.50 for ME/CFS relevance)
- **Limitation:** Hospitalised cohort; ACE2 tropism specific to coronaviruses; generalisability to EBV/enterovirus triggers undemonstrated

H.62.3 Ruiz-Pablos, Paiva & Zabaleta 2024 — Hypocortisolemic ASIA in Long COVID and ME/CFS

Full Citation: Ruiz-Pablos M, Paiva B, Zabaleta A. Hypocortisolemic ASIA: a vaccine- and chronic infection-induced syndrome behind the origin of long COVID and myalgic encephalomyelitis. *Frontiers in Immunology*. 2024;15:1422940. [124]

DOI: [10.3389/fimmu.2024.1422940](https://doi.org/10.3389/fimmu.2024.1422940)

PMID: 39044822 / **PMCID:** PMC11263040

Study Design: Hypothesis/review article; mechanistic model synthesis

Key Findings:

- Proposes that deficient CD4 T-cell viral control in HLA-DRB1 predisposed individuals leads to uncontrolled CD8/antibody response, including autoantibodies against pituitary antigens
- Autoimmune hypophysitis or direct pituitary cytopathic injury reduces ACTH output, producing secondary adrenal insufficiency
- Model predicts a reversibility window: early identification before long-lived autoreactive plasma cells become established may allow recovery of HPA function
- Unifies post-COVID ME/CFS, post-vaccine syndromes, and chronic infection-triggered ME/CFS under a shared neuroendocrine-immune mechanism

Relevance: Provides mechanistic framework connecting viral immune dysregulation to structural pituitary damage. Explains why post-COVID ME/CFS patients with autoimmune hypophysitis present with low-normal cortisol (not flagged by standard screening) and why dynamic testing is essential. The reversibility window concept has direct clinical management implications.

Certainty Assessment:

- **Quality:** Medium (Frontiers in Immunology; hypothesis paper)
- **Sample:** Review/hypothesis; no primary data
- **Replication:** Model consistent with Leow 2005 and Carosi 2024 empirical data
- **Certainty:** 0.40 (hypothesis-level; mechanistically coherent but not directly tested in ME/CFS cohorts)
- **Limitation:** No primary clinical data; HLA-DRB1 specificity not established; vaccine-triggered cases require separate consideration from infection-triggered

H.62.4 Carosi et al. 2024 — Hypopituitarism and COVID-19

Full Citation: Carosi G, Cremaschi A, Giavoli C, Ferrante E, Mantovani G. Hypopituitarism and COVID-19. *Pituitary*. 2024;27(6):925–934. [125]

DOI: [10.1007/s11102-024-01463-3](https://doi.org/10.1007/s11102-024-01463-3)

PMID: 39560821

Study Design: Narrative review of published case series and cohort studies; published November 2024

Key Findings:

- Variable degrees of pituitary deficiency documented across COVID-19 case series
- Both direct viral cytopathic effects and immune-mediated hypophysitis proposed as mechanisms; causation remains uncertain
- Pituitary defects may persist long after acute infection, potentially contributing to long COVID symptom burden
- Heterogeneous results across studies reflect different testing methodologies and hormonal cutoffs

Relevance: Extends SARS-1 evidence (Leow 2005) into COVID-19 context. Documents that pituitary involvement is a feature of SARS-CoV-2 infection. The persistence of pituitary defects post-infection is directly relevant to long COVID and post-COVID ME/CFS HPA dysfunction.

Certainty Assessment:

- **Quality:** Medium-high (Pituitary journal; narrative review)
- **Sample:** Synthesis of multiple case series (heterogeneous)
- **Replication:** Consistent with Leow 2005 SARS-1 data
- **Certainty:** 0.55 (case series quality; causation uncertain; no ME/CFS-specific data)
- **Limitation:** Heterogeneous testing protocols; no ME/CFS-specific data; reversibility unclear

H.63 Meningitis–ME/CFS Intersection

H.63.1 Hotopf et al. 1996 — Chronic Fatigue After Viral Meningitis

Full Citation: Hotopf M, Noah N, Wessely S. Chronic fatigue and minor psychiatric morbidity after viral meningitis: a controlled study. *Journal of Neurology, Neurosurgery and Psychiatry*. 1996;60(5):504–509.

DOI: [10.1136/jnnp.60.5.504](https://doi.org/10.1136/jnnp.60.5.504)

PMID: 8778253

Study Design: Controlled prospective study; 83 post-viral meningitis patients vs. 76 controls with non-enteroviral infections; 6–24 month follow-up

Key Findings:

- CFS prevalence 12.6% in meningitis group
- After adjustment for age, sex, and follow-up duration: OR 1.4 (CI 0.5–3.6), non-significant
- Psychiatric history was the strongest predictor of CFS (OR 7.82)
- The specific viral infection was less important than host factors

Relevance: Only controlled study directly testing meningitis → CFS hypothesis. The 12.6% rate is consistent with the ~11% post-infectious CFS rate from the Dubbo cohort [166], supporting the pathogen-agnostic host-response model. Note: conducted by the Wessely group with biopsychosocial framing; interpretation of psychiatric predictors should be contextualised within the ongoing debate about psychological vs. biological risk factors.

Certainty Assessment: • **Quality:** Medium (controlled design, but small sample)

- **Sample:** $n = 83$ meningitis, $n = 76$ controls
- **Replication:** Not replicated; only study of its kind
- **Certainty:** 0.45 (small sample, old methodology, single study)

H.63.2 Schwitter et al. 2024 — Long-Term Sequelae After Viral Meningitis

Full Citation: Schwitter J et al. Long-term sequelae after viral meningitis and meningoencephalitis. *Frontiers in Neurology*. 2024.

DOI: [10.3389/fneur.2024.1411860](https://doi.org/10.3389/fneur.2024.1411860)

PMID: 39087005

Study Design: Retrospective cohort with structured follow-up questionnaire; 2-year follow-up

Key Findings: • 67% of patients had persistent symptoms at 2 years

- Fatigue/excessive daytime sleepiness in 31%
- 53% reported rapid exhaustion after cognitive effort—functionally equivalent to post-exertional cognitive malaise
- Sleep disturbance in 31%; subjective cognitive impairment in 36%
- Symptoms were independent of acute illness severity

Relevance: The 53% rate of “rapid exhaustion after cognitive effort” essentially describes the cognitive component of PEM. Independence from acute severity parallels ME/CFS, where initial infection severity does not predict chronic outcome. ME/CFS diagnostic criteria were not applied; the actual ME/CFS rate among these survivors is unknown but the symptom profile is highly suggestive.

Certainty Assessment: • **Quality:** Medium-high (large cohort, systematic follow-up)

- **Replication:** Consistent with Ungureanu 2021 (34% fatigue)
- **Certainty:** 0.60 (replicated fatigue finding; but ME/CFS criteria not applied)

H.63.3 Sorensen et al. 2003 — Exercise-Induced Complement Activation in CFS

Full Citation: Sorensen B, Streib JE, Strand M et al. Complement activation in a model of chronic fatigue syndrome. *Journal of Allergy and Clinical Immunology*. 2003;112(2):397–403.

DOI: [10.1067/mai.2003.1615](https://doi.org/10.1067/mai.2003.1615)

PMID: 12897748

Study Design: Controlled exercise challenge; 32 CFS patients, 29 healthy controls

Key Findings: • Significant C4a elevation at 6 hours post-exercise only in CFS group ($P < 0.01$)

- C4a elevation occurred regardless of allergy status
- First demonstration of exercise-induced complement activation in CFS
- Implicates the lectin and/or classical complement pathways in PEM

Relevance: Foundational study linking complement system to PEM mechanism. Subsequently replicated and extended by Nijs 2010 [34], Polli 2019 [35], and Glass 2025 [36] (extracellular vesicle proteomics). The complement–PEM link also connects to meningococcal susceptibility considerations, as complement dysfunction is the strongest known risk factor for invasive meningococcal disease (though the specific pathway differs).

Certainty Assessment:

- **Quality:** High (controlled exercise challenge, rigorous design)
- **Sample:** $n = 61$ total
- **Replication:** Replicated across three independent groups (Nijs, Polli, Glass/Hanson)
- **Certainty:** 0.75 (robust replication; specific mechanism well-characterised)

H.63.4 Iu et al. 2024 — CD8⁺ T Cell Exhaustion in ME/CFS

Full Citation: Iu DS, Maya J, Vu LT et al. Transcriptional reprogramming primes CD8⁺ T cells toward exhaustion in ME/CFS. *Proceedings of the National Academy of Sciences*. 2024;121(50):e2415119121.

DOI: [10.1073/pnas.2415119121](https://doi.org/10.1073/pnas.2415119121)

PMID: 39621903

Study Design: Multi-omics (transcriptomics, epigenomics) characterisation of CD8⁺ T cells

Key Findings:

- Elevated exhaustion markers: SLAMF6, SLAMF7, EOMES, TOX
- Altered metabolic programming with epigenetic signatures of exhaustion
- Demonstrates transcriptional reprogramming toward exhaustion, not merely activation-induced downregulation
- Consistent with chronic antigen stimulation model

Relevance: Landmark study from the Hanson lab (Cornell). Establishes that ME/CFS CD8⁺ T cell dysfunction is an epigenetically programmed state rather than transient activation. Has direct implications for infection susceptibility (exhausted T cells cannot mount effective secondary responses) and vaccine efficacy (whether exhausted T cells can respond to vaccine antigens). The exhaustion phenotype overlaps with Long COVID CD8⁺ dysfunction [47].

Certainty Assessment:

- **Quality:** High (PNAS; multi-omics; rigorous methodology)
- **Replication:** Consistent with Gil 2023 (CD8 dysfunction shared with Long COVID)
- **Certainty:** 0.70 (strong methodology; awaits independent replication)

H.63.5 Piñas et al. 2022 — Glymphatic Dysfunction in Pneumococcal Meningitis

Full Citation: Piñas G et al. Glymphatic system dysfunction in pneumococcal meningitis. *mBio*. 2022.

DOI: [10.1128/mbio.02350-22](https://doi.org/10.1128/mbio.02350-22)

PMID: 36286550

Study Design: Preclinical (murine pneumococcal meningitis model)

Key Findings:

- Progressive retraction of astrocytic endfeet from vascular endothelium

- Misplacement of AQP4 water channels preventing CSF-interstitial fluid exchange
- Accumulation of bacterial toxins (pneumolysin) in CSF compartments
- Increased microglial activation, brain damage, and memory impairment

Relevance: Proposes glymphatic dysfunction as “a new pathomechanism in pneumococcal meningitis” explaining long-term neurological sequelae. Directly parallels the ME/CFS glymphatic dysfunction hypothesis [45]. The AQP4 misplacement mechanism provides a specific molecular target that could be assessed in ME/CFS patients via post-mortem studies or advanced MRI techniques.

Certainty Assessment: • **Quality:** High (mBio; well-controlled animal model)

- **Replication:** Novel finding; not yet replicated
- **Certainty:** 0.55 (animal model; human translation uncertain)

H.63.6 Christodoulides et al. 2025 — Dural Mast Cells Regulate CSF Dynamics

Full Citation: Christodoulides M et al. Dural mast cells regulate CSF dynamics at arachnoid cuff exit points. *Cell*. 2025.

DOI: [10.1016/j.cell.2025.06.046](https://doi.org/10.1016/j.cell.2025.06.046)

PMID: 40712577

Study Design: Preclinical (murine); combining mast cell-deficient mice, bacterial meningitis models, and advanced CSF imaging

Key Findings: • Dural mast cells regulate CSF dynamics at arachnoid cuff exit (ACE) points

- During meningitis, mast cell activation redirects CSF flow and recruits neutrophils
- Mice lacking dural mast cells had impaired immune responses and higher brain bacterial loads
- Histamine release induces vasodilation of bridging veins, reducing perivascular spaces for CSF drainage

Relevance: Landmark Cell paper creating a previously unrecognised mechanistic bridge between mast cell activation and glymphatic/CSF flow regulation. If chronic mast cell dysfunction (MCAS) disrupts CSF flow at ACE points, this connects the ME/CFS-associated MCAS phenotype to glymphatic waste clearance impairment via a non-inflammatory mechanism. This is the strongest mechanistic link between mast cell pathology and the cognitive symptoms of ME/CFS that does not invoke systemic inflammation.

Certainty Assessment: • **Quality:** Very high (Cell; rigorous multi-model approach)

- **Replication:** Novel discovery; not yet replicated
- **Certainty:** 0.60 (animal model; human translation pending; ME/CFS application is extrapolation)

H.63.7 Magnus et al. 2015 — Infection, Not Vaccination, Triggers CFS/ME

Full Citation: Magnus P et al. CFS/ME is associated with pandemic influenza infection, but not with an adjuvanted pandemic influenza vaccine. *Vaccine*. 2015;33(46):6173–6177.

DOI: [10.1016/j.vaccine.2015.10.018](https://doi.org/10.1016/j.vaccine.2015.10.018)

PMID: 26475444

Study Design: Population-based registry study; entire Norwegian population 2009–2012

Key Findings: • Pandemic influenza infection: HR 2.04 (CI 1.78–2.33) for CFS/ME

- Adjuvanted pandemic vaccine (Pandemrix): HR 0.97 (no increased risk)
- Complete separation of infection risk from vaccination risk at population level

Relevance: Definitive population-level evidence that infection, not antigen exposure, triggers CFS/ME. Combined with the meningococcal vaccine safety data (Magnus 2009, OR 1.06) [30], establishes that vaccination is protective (prevents infection-triggered CFS/ME) without adding CFS/ME risk. Critical for clinical decision-making about vaccination in ME/CFS patients.

Certainty Assessment: • **Quality:** Very high (entire national population; registry-based)

- **Sample:** Millions of person-years
- **Certainty:** 0.85 (population-level data; definitive for influenza/Pandemrix; generalisation to other vaccines is reasonable but not directly tested)

I Ongoing and Planned ME/CFS Research Studies

This appendix catalogues major ongoing and planned research studies in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). Each entry provides structured metadata—principal investigator, institution, registry identifiers, cohort size, and study focus—followed by a brief discussion of the study’s potential to advance ME/CFS understanding.

Data sources. Entries were compiled from ClinicalTrials.gov, the ISRCTN registry, institutional announcements, and the Solve ME/CFS Initiative trial tracker. Registry identifiers (NCT numbers, ISRCTN numbers) are included where available.

Currency. This registry was last updated on 2026-03-07. Study status information may have changed since that date; readers should verify current status via the URLs provided.

Scope. The registry includes studies that are actively recruiting, enrolled, or in analysis as of the currency date, plus selected planned studies with confirmed funding. Completed studies with published results are covered in the main text and Appendix H.

⚠ Limitation 1: Registry Completeness

This registry is necessarily incomplete. Smaller institutional studies, industry-sponsored trials in early phases, and studies registered outside ClinicalTrials.gov or ISRCTN may not be captured. Inclusion does not imply endorsement of study design or methodology; exclusion does not imply irrelevance.

I.1 Multi-Omics and Systems Biology

I.1.1 Rosetta Stone Study

Principal Investigator: Danny Altmann, Professor of Immunology

Institution: Imperial College London, United Kingdom

Contact/URL: <https://meassociation.org.uk/2025/12/driving-discovery-the-me-association-inv>

Funder: ME Association, Ramsay Research Fund

Status: Active (recruitment began late 2025)

Phase: Observational, multi-omics

Cohort: 250 ME/CFS + 250 Long Covid + matched healthy controls

Mechanism/Focus: Side-by-side cellular and molecular analyses of ME/CFS and Long Covid. Stool, blood, and saliva samples analysed across multiple omics platforms, with machine learning applied to discover shared molecular pathways between the two conditions. Partnership with ELAROS for digital phenotyping.

Primary Outcomes: Shared and distinguishing molecular signatures between ME/CFS and Long Covid; candidate biomarkers

Estimated Completion: 2028 (3-year study)

Timeline: Recruitment started Q4 2025; 3-month progress update published March 2026; interim analysis expected mid-study

Publication Medium: Not yet announced; likely high-impact immunology or multidisciplinary journal; open access expected given charity funding

Document Relevance: Ch. 7 (immune dysfunction), Ch. 11 (gut microbiome), Ch. 13 (integrative models), Ch. 14 §14.17 (cross-disease comparison)

The Rosetta Stone Study represents the largest single investment in ME/CFS biomedical research by a UK charity (£1.1M). Its defining strength is the parallel recruitment of ME/CFS and Long Covid cohorts with identical multi-omics profiling, enabling direct molecular comparison of two conditions widely hypothesised to share pathophysiological mechanisms. If the study identifies shared immune or metabolic signatures, it could accelerate biomarker development by leveraging the larger Long Covid research infrastructure. The inclusion of stool samples positions the study to contribute microbiome data that remains scarce in well-phenotyped ME/CFS cohorts.

I.1.2 BioQuest Study

Principal Investigator: Jonas Bergquist (proteomics lead); coordinated by Open Medicine Foundation (OMF) research team

Institution: Uppsala University (Sweden) and Open Medicine Foundation collaborative centres

Contact/URL: <https://ns1.omf.ngo/bioquest-update/>

Funder: Open Medicine Foundation

Status: Active (sample collection complete; analysis phase)

Phase: Observational, multi-omics biomarker discovery

Cohort: 400 ME/CFS + 400 healthy controls + 200 disease controls (50 each: multiple sclerosis, burnout syndrome, depression, Long Covid). Combines samples from the Uppsala Collaborative Centre and the NIH Chronic Fatigue Initiative biobank.

Mechanism/Focus: Large-scale metabolomics, lipidomics, proteomics, and cytokine profiling (>10,000 analytes) with AI-driven subgroup identification. Goal: identify a 5–20 protein/metabolite biomarker panel unique to ME/CFS.

Primary Outcomes: Validated ME/CFS biomarker panel; biologically defined patient subgroups

Estimated Completion: Results expected 2026–2027

Timeline: Sample integration approved 2025; testing began late 2025; bioinformatic analysis ongoing

Publication Medium: Expected in high-impact journal; OMF typically publishes open access

Document Relevance: Ch. 6 (energy metabolism), Ch. 7 (immune dysfunction), Ch. 13 (integrative models), Ch. 20 (biomarker research)

BioQuest is the largest ME/CFS biomarker study to date by sample size ($n = 1,000$). Its inclusion of disease controls (MS, depression, burnout, Long Covid) directly addresses a longstanding criticism that ME/CFS biomarker candidates lack disease specificity. The multi-omics approach measuring over 10,000 analytes, combined with AI-driven clustering, has realistic potential to identify biologically defined subgroups—a prerequisite for precision medicine approaches. If successful, BioQuest could provide the first blood-based diagnostic panel capable of distinguishing ME/CFS from conditions with overlapping symptom profiles.

I.2 Genomics and Epigenetics

I.2.1 DecodeME

Principal Investigator: Chris Ponting, Professor of Medical Bioinformatics

Institution: University of Edinburgh, United Kingdom

Contact/URL: <https://www.decode.me.org.uk/>

Registry ID: ISRCTN15960771

Funder: MRC/NIHR (UK Research and Innovation)

Status: Active (genotyping and analysis phase)

Phase: Observational, genome-wide association study (GWAS)

Cohort: >20,000 ME/CFS patients (DNA samples); UK-based, self-reported diagnosis with GP confirmation

Mechanism/Focus: First large-scale GWAS for ME/CFS. Aims to identify genetic variants associated with susceptibility, severity, and symptom subtypes. DNA collected via saliva kits mailed to participants.

Primary Outcomes: Genome-wide significant loci for ME/CFS; genetic correlation with related conditions; polygenic risk scores

Estimated Completion: First results expected 2026

Timeline: Recruitment launched 2022; sample collection completed 2024; genotyping in progress; first GWAS results anticipated 2026

Publication Medium: Expected in genetics/genomics journal (e.g., *Nature Genetics*); open access

Document Relevance: Ch. 12 (genetic and epigenetic factors), Ch. 20 (biomarker research), Ch. 23 (epidemiology)

DecodeME is unprecedented in ME/CFS genetics: with over 20,000 participants, it has the statistical power to detect common variants of modest effect size that previous underpowered GWAS could not identify. Genetic findings could reveal causal pathways (e.g., immune regulation, ion channel function, autonomic control) and enable Mendelian randomisation analyses to test whether associations observed in smaller studies reflect causal relationships. The study's scale also allows subgroup analyses by onset trigger, severity, and symptom profile.

I.2.2 EpiSwitch CFS Epigenetic Diagnostic

Principal Investigator: Ewan Hunter (lead author, validation study)

Institution: Oxford BioDynamics, United Kingdom

Contact/URL: <https://doi.org/10.1186/s12967-025-07203-w>

Registry ID: N/A (proof-of-concept; clinical validation pending)

Funder: Oxford BioDynamics (industry)

Status: Proof-of-concept published October 2025; clinical validation studies planned

Phase: Diagnostic development (pre-clinical validation)

Cohort: Initial study: 47 severe ME/CFS patients + 61 healthy controls. Larger validation cohorts needed.

Mechanism/Focus: EpiSwitch 3D genomic profiling of chromosome conformation captures (CCs) in blood. Identified a 200-marker epigenetic model. Pathways implicated: interleukins, TNF α , neuroinflammation, toll-like receptor signalling, JAK/STAT.

Primary Outcomes: Sensitivity 92%, specificity 98%, overall accuracy 96% in proof-of-concept validation cohort

Estimated Completion: Clinical validation timeline not yet announced

Timeline: Proof-of-concept published October 2025; independent replication and prospective validation required before clinical use

Publication Medium: *Journal of Translational Medicine* (published); future validation studies TBD

Document Relevance: Ch. 12 (genetic and epigenetic factors), Ch. 20 (biomarker research), Ch. 25 (translational findings)

The EpiSwitch proof-of-concept achieved striking diagnostic accuracy (96%), but the small sample size ($n = 108$) and retrospective design warrant caution. If validated in larger, prospective, multi-site cohorts with disease controls, this approach could provide the first epigenetic blood test for ME/CFS. The implicated pathways (JAK/STAT, TLR signalling, neuroinflammation) align with immune findings reported in Chapters 7 and 8, providing convergent evidence from an independent methodological angle. The critical next step is independent replication with blinded samples.

I.2.3 PrecisionLife Combinatorial Genomics

Principal Investigator: Steve Gardner (CEO, PrecisionLife)

Institution: PrecisionLife Ltd, Oxford, United Kingdom

Contact/URL: <https://precisionlife.com/news-and-events/me-genetics-study>

Registry ID: N/A (secondary analysis of DecodeME and UK Biobank data)

Funder: PrecisionLife (industry) with access to DecodeME consortium data

Status: Published December 2025

Phase: Computational genomics (AI-led combinatorial analytics)

Cohort: Two DecodeME cohorts + UK Biobank; results confirmed across three independent datasets

Mechanism/Focus: Applied combinatorial analytics platform to identify gene–gene interaction networks in ME/CFS. Unlike standard GWAS (which tests single variants), this approach identifies combinations of variants that jointly confer risk.

Primary Outcomes: Identified 250+ core genes associated with ME/CFS, of which 76 genes overlap with long COVID. Networks cluster around immune regulation, metabolic function, and neurological pathways.

Estimated Completion: Published

Publication Medium: PrecisionLife press release and preprint; peer-reviewed publication expected

Document Relevance: Ch. 12 (genetic factors), Ch. 13 (integrative models), Ch. 14 §14.17 (long COVID overlap)

The PrecisionLife analysis complements the DecodeME GWAS (Section 1.2.1) by detecting higher-order gene–gene interactions that conventional single-variant approaches miss. The 76-gene overlap with long COVID provides the strongest genetic evidence yet for shared biological mechanisms between the two conditions, supporting the hypothesis explored in Ch. 14 §14.17. However, combinatorial approaches can generate false positives when the number of tested combinations is large; independent replication (ideally in non-European ancestries) is essential before clinical or mechanistic conclusions are drawn. [845]

1.3 Biomarker Discovery and Diagnostics

1.3.1 BioMapAI (Gut Microbiome and Metabolomics)

Principal Investigator: Derya Unutmaz (Jackson Laboratory); AI platform developed with Duke University

Institution: Jackson Laboratory (JAX) and Duke University School of Medicine, United States

Contact/URL: <https://medschool.duke.edu/news/ai-thats-finally-making-sense-chronic-fatigue>

Funder: NIH and institutional funding

Status: Active (longitudinal follow-up ongoing)

Phase: Observational, AI-integrated multi-omics

Cohort: 153 ME/CFS patients + 96 healthy controls, followed longitudinally over 4 years

Mechanism/Focus: AI platform integrating gut metagenomics, plasma metabolomics, immune cell profiles, standard blood tests, and clinical symptoms. Achieved 90% accuracy in distinguishing ME/CFS from controls. Identified gut microbiome signatures as strong predictors.

Primary Outcomes: Multi-modal diagnostic classifier; longitudinal trajectory modelling; microbiome-metabolome interaction networks

Estimated Completion: Ongoing longitudinal follow-up; initial results published 2025

Timeline: Recruitment 2020–2023; initial AI classifier published July 2025; longitudinal analysis ongoing

Publication Medium: Initial results in high-impact journal (2025); longitudinal follow-up expected 2026–2027

Document Relevance: Ch. 11 (gut microbiome), Ch. 6 (energy metabolism), Ch. 13 (integrative models), Ch. 20 (biomarker research)

BioMapAI is notable for its longitudinal design and AI-first analytical approach. Unlike cross-sectional biomarker studies, the 4-year follow-up can capture disease trajectory and distinguish state markers (fluctuating with symptoms) from trait markers (stable features of the disease). The gut microbiome component strengthens the microbiome–immune–metabolism axis described in Chapter 11. The 90% classification accuracy, while promising, requires external validation in independent cohorts.

I.3.2 ME Association PhD Project (Metabolite and Infection Markers)

Principal Investigator: Aleya Lumsden (PhD candidate); supervised across multiple institutions

Institution: Rosalind Franklin Institute, Imperial College London, and National Phenome Centre, United Kingdom

Contact/URL: <https://meassociation.org.uk/2025/11/research-new-funding-awarded-to-phd-project>

Funder: ME Association Ramsay Research Fund and UKRI (joint)

Status: Active (PhD project started 2025)

Phase: Observational, metabolomics and infection biomarkers

Cohort: To be determined (likely leveraging existing biobank samples)

Mechanism/Focus: Advanced mass spectrometry and informatics to identify unknown metabolites and uncover evidence of infection in ME/CFS. Uses facilities across three major UK research centres.

Primary Outcomes: Novel metabolite identification; infection marker discovery; candidate biomarkers for further validation

Estimated Completion: 2028–2029 (typical PhD duration)

Timeline: Funding awarded November 2025; project started 2025–2026

Publication Medium: PhD thesis and associated journal publications

Document Relevance: Ch. 6 (energy metabolism), Ch. 7 (immune dysfunction), Ch. 20 (biomarker research)

This PhD project complements the larger Rosetta Stone Study by focusing specifically on unknown metabolites—compounds not yet characterised in standard metabolomics panels. The infection marker component addresses the long-standing hypothesis that persistent or reactivated infections drive ME/CFS pathology (Chapter 7). Access to the Rosalind Franklin Institute’s advanced mass spectrometry facilities gives this project analytical capabilities beyond typical academic metabolomics studies.

I.3.3 MEA–UCL Blood Biomarker Pilot

Principal Investigator: Sophie Hicks (PhD student); supervisors Dr. Amanda Heslegrave, Dr. Michael Zandi, Prof. Henrik Zetterberg

Institution: UK DRI Fluid Biomarker Laboratory, UCL Institute of Neurology, London

Contact/URL: ME Association announcement, February 2026

Registry ID: Not yet registered (pilot/observational)

Funder: ME Association (UK)

Status: Active (12-month project, started February 2026)

Phase: Observational pilot

Cohort: Blood samples from ME/CFS patients (UK ME/CFS Biobank), Long Covid patients (UCLH STIMULATE-ICP study), and healthy volunteers

Mechanism/Focus: Searches for blood-based biomarkers linking specific symptom clusters (brain fog, headaches, muscle pain) to measurable biological changes. Applies neuroimmunology expertise from the Zetterberg group (world-leading in fluid biomarkers for neurodegeneration, e.g., neurofilament light chain).

Primary Outcomes: Candidate blood biomarkers correlated with symptom clusters

Estimated Completion: ~February 2027

Timeline: 12-month pilot; may lead to larger validation study

Publication Medium: Not yet announced

Document Relevance: Ch. 7 (immune dysfunction), Ch. 22 (mechanistic studies)

The Zetterberg laboratory's involvement is notable: their deep expertise in neurofilament light chain and related neurodegeneration biomarkers has not previously been applied to ME/CFS. Cross-disease biomarker candidates (shared between ME/CFS and neurodegenerative conditions) could emerge from this work, informing the diagnostic overlap discussion in Chapter 14.17.

I.3.4 Cornell Cell-Free RNA Liquid Biopsy

Principal Investigator: Iwijn De Vlaminck (Biomedical Engineering) and Maureen Hanson (Molecular Biology and Genetics)

Institution: Cornell University, Ithaca, NY

Contact/URL: <https://doi.org/10.1073/pnas.2507345122>

Funder: NIH / institutional

Status: Published August 2025

Phase: Biomarker discovery (cross-sectional)

Cohort: 93 ME/CFS cases + 75 healthy sedentary controls

Mechanism/Focus: Profiled circulating cell-free RNA (cfRNA) in plasma by RNA sequencing. Identified over 700 differentially expressed transcripts. Immune cfRNA deconvolution revealed elevated plasmacytoid dendritic cell, monocyte, and T cell-derived cfRNA in ME/CFS, with signatures of cytokine signalling and T cell exhaustion.

Primary Outcomes: GLM-LASSO classifier AUC 0.81, accuracy 77%. Not yet diagnostic-grade but substantial advance over prior attempts

Estimated Completion: Published

Publication Medium: *Proceedings of the National Academy of Sciences*

Document Relevance: Ch. 7 (immune dysfunction), Ch. 20 (biomarker research), Ch. 25 (translational findings)

Cell-free RNA offers a minimally invasive “liquid biopsy” approach that captures tissue-level biology without biopsies. The 77% classification accuracy is insufficient for a standalone diagnostic but demonstrates that cfRNA carries ME/CFS-relevant biological signal [328]. The T cell exhaustion and platelet activation signatures align with independent findings from single-cell transcriptomics (Section I.9.1) and proteomics (Section I.3.5). Prospective validation in a larger, multi-site cohort with disease controls (fibromyalgia, depression, long COVID) is needed to assess clinical utility.

I.3.5 Cell Reports Medicine Multi-Modal Study

Principal Investigator: Multiple collaborating groups

Institution: Multi-centre (USA)

Contact/URL: <https://doi.org/10.1016/j.xcrm.2025.102012>

Funder: NIH / institutional

Status: Published 2025

Phase: Observational, multi-modal

Cohort: ME/CFS patients + healthy controls

Mechanism/Focus: Integrated energy metabolism assessment, immune profiling, and plasma proteomics. Immune cells from ME/CFS patients showed elevated AMP and ADP with reduced ATP/ADP ratio. NK cell and dendritic cell subset abnormalities. Vascular dysfunction markers including soluble THBS1, VWF, and VASN.

Primary Outcomes: Converging evidence across energy, immune, and vascular axes; reduced CD56^{low}CD16⁺ NK cells (antiviral), increased plasmacytoid DCs

Estimated Completion: Published

Publication Medium: *Cell Reports Medicine*

Document Relevance: Ch. 6 (energy metabolism), Ch. 7 (immune dysfunction), Ch. 10 (cardiovascular), Ch. 13 (integrative models)

This study is noteworthy for its simultaneous assessment of three pathophysiological axes—energy, immune, and vascular—in the same cohort, enabling correlation analyses that single-axis studies cannot perform [295]. The reduced ATP/ADP ratio in immune cells provides a mechanistic link between energy metabolism (Ch. 6) and immune dysfunction (Ch. 7). The vascular findings (elevated thrombospondin-1, von Willebrand factor) converge with coagulation abnormalities reported in the microclot literature [292].

I.4 Autoimmunity and Immunomodulation

I.4.1 Charité Immunoadsorption Trial (IA-PACS-CFS)

Principal Investigator: Carmen Scheibenbogen, MD, Professor of Immunology

Institution: Charité – Universitätsmedizin Berlin, Charité Fatigue Centrum, Germany

Contact/URL: https://cfc.charite.de/en/clinical_research/nksg/trial_ia_pacs_cfs

Registry ID: NCT05710770

Funder: Institutional and ME/CFS Research Foundation

Status: Active (double-blind, sham-controlled)

Phase: Exploratory interventional trial

Cohort: ME/CFS patients (post-COVID and other post-infectious) with elevated β_2 -adrenergic receptor autoantibodies

Mechanism/Focus: Five immunoadsorption sessions over 10 days to remove pathogenic autoantibodies targeting G-protein coupled receptors (GPCRs), compared with sham treatment. Prior open-label cohort ($n = 20$) showed clinical improvement.

Primary Outcomes: Clinical improvement at 3 months (Chalder Fatigue Scale); autoantibody levels; 6-month follow-up

Estimated Completion: Not yet announced

Timeline: Open-label cohort 2022–2023 (published January 2025); double-blind RCT ongoing

Publication Medium: Open-label results in peer-reviewed journal (2025); RCT results expected in high-impact immunology journal

Document Relevance: Ch. 7 (immune dysfunction—autoantibodies), Ch. 10 (autonomic dysfunction), Ch. 19 (integrative approaches)

The Charité immunoadsorption programme is the most advanced clinical investigation of the autoantibody hypothesis in ME/CFS. Scheibenbogen's group has systematically built from case reports through an open-label cohort to a sham-controlled RCT—the methodological progression needed to establish causality. The requirement for elevated β_2 -adrenergic receptor autoantibodies as an inclusion criterion represents a biomarker-stratified trial design, testing both the treatment and the underlying autoimmune mechanism simultaneously. A new 2026-funded neuroimaging substudy will assess whether thalamocortical hyperconnectivity normalises after immunoadsorption, linking peripheral autoimmunity to central nervous system changes.

I.4.2 BC007 (Rovunaptabin) Phase II Trials

Principal Investigator: Multiple (industry-sponsored)

Institution: Berlin Cures GmbH, Germany (multi-site)

Contact/URL: <https://clinicaltrials.gov/study/NCT05911009>

Registry ID: NCT05911009 (Phase II, $n = 114$); earlier Phase IIa ($n = 29$)

Funder: Berlin Cures GmbH (industry)

Status: Phase II completed/in analysis

Phase: Phase IIa (crossover, $n = 29$) and Phase II ($n = 114$)

Cohort: Post-COVID syndrome patients with functional GPCR autoantibodies and predominant fatigue

Mechanism/Focus: Rovunaptabin (BC007) is an aptamer that neutralises functional autoantibodies against GPCRs. Unlike immunoadsorption (which removes all immunoglobulins non-selectively), BC007 targets pathogenic autoantibodies specifically.

Primary Outcomes: Fatigue severity; autoantibody neutralisation; safety

Estimated Completion: Results expected 2026

Timeline: Phase IIa enrolled 29 patients; Phase II enrolled 114 patients; analysis ongoing

Publication Medium: Not yet announced; industry-sponsored trials typically target high-impact journals

Document Relevance: Ch. 7 (immune dysfunction—autoantibodies), Ch. 25 (translational findings)

BC007 and immunoadsorption represent complementary approaches to the same autoantibody hypothesis: immunoadsorption removes antibodies broadly, while BC007 neutralises specific pathogenic autoantibodies in situ. The Phase II trial ($n = 114$) is the largest RCT testing autoantibody-targeted therapy in post-infectious fatigue conditions. Positive results would validate the functional GPCR autoantibody hypothesis and open a pharmacological treatment pathway. However, the trials enrolled post-COVID patients specifically; extension to non-COVID ME/CFS cohorts will be needed.

I.4.3 ResetME Trial (Daratumumab)

Principal Investigator: Øystein Flüge and Olav Mella

Institution: Haukeland University Hospital, Bergen, Norway (with Oslo University Hospital)

Contact/URL: EudraCT / EU Clinical Trials Register

Registry ID: European registry (no NCT number)

Funder: ME Fund Norway; institutional

Status: Recruiting (opened June 2025)

Phase: Phase II, randomised, double-blind, placebo-controlled (2:1 ratio)

Cohort: 66 participants; moderate-to-severe ME/CFS (CCC criteria), minimum 2-year disease duration

Mechanism/Focus: Daratumumab is an anti-CD38 monoclonal antibody that depletes plasma cells, causing transient reduction of pathogenic autoantibodies (including anti-adrenergic and anti-cholinergic receptor antibodies). Follow-on from the open-label KTS9 pilot ($n = 10$, EudraCT 2022-000281-18), in which 6/10 patients showed marked improvement and mean SF-36 Physical Function rose from 25.9 to 55.0.

Primary Outcomes: Symptom reduction (SF-36 Physical Function); safety

Estimated Completion: ~2027 (72-week total participation)

Timeline: 26-week treatment period, 72-week follow-up from June 2025 start

Publication Medium: Not yet announced; pilot published in *Frontiers in Medicine*, June 2025

Document Relevance: Ch. 7 (immune dysfunction—autoantibodies), Ch. 10 (adrenergic receptor autoantibodies), Ch. 19 (integrative approaches)

ResetME is among the highest-priority ongoing ME/CFS trials. Flüge and Mella are the same

group that conducted the rituximab trials; daratumumab targets plasma cells more selectively via CD38. Unlike rituximab (which depletes CD20+ B cells), daratumumab directly reduces the antibody-secreting plasma cells hypothesised to produce pathogenic autoantibodies. The pilot response rate (60%, with near-doubling of physical function scores) is among the strongest signals in ME/CFS treatment research. If the RCT replicates these findings, it would establish the first disease-modifying treatment for an autoimmune subset of ME/CFS. Combined with BC007 (Section I.4.2) and immunoadsorption (Section I.4.1), this trial represents the third independent approach to the autoantibody hypothesis.

I.5 Neuroimaging and Ion Channel Research

I.5.1 NCNED TRPM3 Ion Channel Programme

Principal Investigator: Sonya Marshall-Gradisnik, Professor of Immunology

Institution: National Centre for Neuroimmunology and Emerging Diseases (NCNED), Griffith University, Australia

Contact/URL: <https://www.griffith.edu.au/research/health/national-centre-neuroimmunology-en>

Funder: Institutional and NHMRC (Australia)

Status: Active (multiple ongoing studies)

Phase: Observational and interventional (LDN trials planned)

Cohort: ME/CFS and Long Covid patients (multiple cohorts)

Mechanism/Focus: Systematic investigation of TRPM3 ion channel dysfunction in ME/CFS. January 2026 publication confirmed consistent TRPM3 malfunction using gold-standard patch-clamp techniques. Also conducting 7T MRI studies revealing hippocampal volume alterations. Preparing LDN clinical trials for both ME/CFS and Long Covid.

Primary Outcomes: TRPM3 channel function; hippocampal volume changes; LDN trial endpoints TBD

Estimated Completion: Ongoing programme (multiple studies)

Timeline: TRPM3 confirmation published January 2026; 7T MRI study published February 2025; LDN trials in preparation; \$438,000 grant for longitudinal brain imaging (progression study)

Publication Medium: Published in *PLOS ONE* and specialty journals; future publications expected similarly

Document Relevance: Ch. 8 (neurological dysfunction), Ch. 7 (immune dysfunction—ion channels), Ch. 20 (biomarker research)

The NCNED programme is distinctive for its sustained, systematic focus on a single molecular target (TRPM3) across multiple methodologies. The January 2026 patch-clamp confirmation elevates TRPM3 dysfunction from an association to a consistently reproducible cellular phenotype—a rare achievement in ME/CFS research. The planned LDN trials will test whether modulating neuroinflammation (a proposed upstream driver of ion channel dysfunction) improves TRPM3 function and clinical outcomes, creating a mechanistic link between

treatment and pathophysiology. The 7T MRI hippocampal findings add a neuroanatomical dimension that connects to cognitive complaints reported by patients.

I.5.2 Charité Neuroimaging Biomarker Study

Principal Investigator: Carmen Scheibenbogen, MD (PI); neuroimaging team at Charité

Institution: Charité – Universitätsmedizin Berlin, Germany

Contact/URL: <https://mecfs-research.org/en/researchfunding-charite-biomarker2/>

Funder: ME/CFS Research Foundation (Germany)

Status: Funded; starting January 2026

Phase: Observational (neuroimaging biomarker development)

Cohort: ME/CFS patients undergoing immunoadsorption treatment

Mechanism/Focus: Investigates whether functional brain changes— particularly thalamo-cortical hyperconnectivity—can be modulated by immunoadsorption. Tests whether CNS abnormalities normalise after peripheral autoantibody removal, linking the autoimmune and neurological hypotheses.

Primary Outcomes: Pre/post-treatment fMRI connectivity changes; correlation with clinical improvement and autoantibody levels

Estimated Completion: Not yet announced (recently funded)

Timeline: Funding confirmed late 2025; project starting January 2026

Publication Medium: Not yet announced

Document Relevance: Ch. 8 (neurological dysfunction), Ch. 7 (immune dysfunction—autoantibodies), Ch. 13 (integrative models)

This study bridges two major ME/CFS hypotheses: autoimmunity and central nervous system dysfunction. By imaging the brain before and after immunoadsorption, it can test whether peripheral autoantibody removal reverses central connectivity abnormalities—a question that goes beyond symptom improvement to mechanistic understanding. If thalamocortical hyperconnectivity normalises with autoantibody reduction, it would provide the strongest evidence yet that peripheral immune dysregulation drives CNS pathology in ME/CFS rather than the reverse.

I.5.3 Hyperbaric Oxygen Therapy for ME/CFS

Principal Investigator: Multiple PIs

Institution: Multi-site (USA / Germany)

Contact/URL: <https://doi.org/10.1101/2025.10.29.25339096>

Registry ID: NCT06118138 (post-COVID/ME/CFS HBOT study)

Funder: ME/CFS Research Foundation / institutional

Status: Pilot results published (preprint October 2025); larger RCT in planning

Phase: Phase 1–2 (open-label pilot)

Cohort: $n = 30$ ME/CFS patients, 40 HBOT sessions each

Mechanism/Focus: Hyperbaric oxygen therapy (2.4 ATA, 100% O₂) to address tissue hypoxia, neuroinflammation, and endothelial dysfunction. Pre- and post-treatment fMRI assessed thalamic connectivity.

Primary Outcomes: SF-36 physical functioning significantly improved. Exercise capacity, muscle strength, and information processing speed all improved. Thalamic hyperconnectivity normalised post-HBOT

Estimated Completion: Pilot published; RCT timeline TBD

Publication Medium: medRxiv preprint; peer review pending

Document Relevance: Ch. 8 (neurological dysfunction), Ch. 10 (cardiovascular), Ch. 19 (integrative approaches)

The normalisation of thalamic hyperconnectivity after HBOT provides the most direct interventional evidence to date linking brain connectivity abnormalities to a treatable target in ME/CFS [846]. However, the open-label design and small sample size preclude definitive conclusions; placebo effects are substantial for fatigue interventions, and a sham-controlled design (e.g., 1.3 ATA room air) is essential. The overlap with brainstem hypoperfusion research strengthens the rationale for oxygen-targeting approaches.

I.6 Large-Scale Federally Funded Programmes

I.6.1 RECOVER-TLC Clinical Trials Programme

Principal Investigator: Multiple PIs across sites

Institution: NIH-funded, multi-site across the United States

Contact/URL: <https://recovercovid.org/>

Registry ID: Multiple NCT numbers (programme-level)

Funder: NIH (National Institutes of Health)

Status: Active; multiple trials at different stages

Phase: Multiple interventional trials (Phase II–III)

Cohort: Long Covid patients (with substantial ME/CFS overlap)

Mechanism/Focus: The RECOVER-Treating Long COVID (TLC) programme includes multiple treatment trials:

- **REVERSE-LC:** Baricitinib (JAK inhibitor) for neurocognitive and cardiopulmonary symptoms; recruiting
- **RECOVER Energize:** Structured pacing for PEM ($n = 600$); completing December 2025
- **LDN trial:** Low-dose naltrexone for fatigue in ages 6–25; enrolment estimated summer 2026
- **GLP-1 agonist trial:** Targeting immune dysregulation; enrolment estimated late summer 2026

Primary Outcomes: Vary by trial; include symptom severity, exercise tolerance, immune markers, quality of life

Estimated Completion: Results from first-round trials expected by end of 2026

Timeline: RECOVER programme initiated 2021; TLC trials began 2024–2025; second-round trials planning 2026

Publication Medium: High-impact journals; all results expected to be open access (NIH-funded)

Document Relevance: Ch. 7 (immune dysfunction), Ch. 10 (cardiovascular), Ch. 17 (pacing), Ch. 14 §14.17 (cross-disease)

RECOVER-TLC is the largest federally funded treatment trial programme relevant to ME/CFS. While focused on Long Covid, the substantial clinical overlap means positive results are directly translatable. The baricitinib (JAK inhibitor) trial is particularly noteworthy given the JAK/STAT pathway abnormalities identified in ME/CFS (Chapter 7) and the EpiSwitch epigenetic findings. The structured pacing trial (RECOVER Energize, $n = 600$) will provide the first large-scale evidence for pacing—the most widely recommended non-pharmacological intervention in ME/CFS—in a rigorous clinical trial framework. The paediatric LDN trial fills a critical gap, as most ME/CFS treatment evidence excludes children and adolescents.

I.7 Clinical Trials (Interventional)

I.7.1 LIFT Trial (Low-Dose Naltrexone and Pyridostigmine)

Principal Investigator: David Systrom, MD

Institution: Brigham and Women's Hospital, Harvard Medical School, United States

Contact/URL: <https://solvecfs.org/exploring-current-me-cfs-and-long-covid-clinical-trials->

Funder: Solve ME/CFS Initiative (Ramsay Research Grant)

Status: Recruiting

Phase: Clinical trial (interventional)

Cohort: ME/CFS patients (specific n to be confirmed)

Mechanism/Focus: Tests whether low-dose naltrexone (LDN) and pyridostigmine reduce symptoms and improve quality of life. LDN targets neuroinflammation via glial cell modulation; pyridostigmine is an acetylcholinesterase inhibitor used for autonomic dysfunction.

Primary Outcomes: Symptom severity; quality of life measures

Estimated Completion: Not yet announced

Timeline: Recruitment ongoing as of 2026

Publication Medium: Not yet announced

Document Relevance: Ch. 16 (supplements and nutraceuticals), Ch. 10 (cardiovascular/autonomic), Ch. 17 (lifestyle interventions)

The LIFT trial addresses two of the most widely used off-label treatments in ME/CFS clinical practice. LDN has accumulated substantial anecdotal and preliminary evidence (Chapter 16) but lacks rigorous RCT data in ME/CFS specifically. Pyridostigmine targets the preload failure mechanism identified in invasive cardiopulmonary exercise testing by Systrom's own

group (Chapter 10). A positive result could provide the first high-quality evidence base for two treatments already in widespread empirical use.

I.7.2 UAB LDN Dose-Finding Study

Principal Investigator: Jarred Younger, PhD

Institution: University of Alabama at Birmingham, United States

Contact/URL: <https://clinicaltrials.gov/study/NCT07285473>

Registry ID: NCT07285473

Funder: Institutional

Status: Recruiting (remote/decentralised, US-wide)

Phase: Dose-finding study

Cohort: Adults with ME/CFS (specific *n* TBD)

Mechanism/Focus: Dose-finding study for low-dose naltrexone in ME/CFS. Distinct from the LIFT trial (which combines LDN with pyridostigmine, Section I.7.1) and the RECOVER paediatric LDN trial (Section I.6.1): this study focuses on determining optimal adult LDN dosing specifically for ME/CFS. Remote design enables broad US enrolment.

Primary Outcomes: Dose-response for symptom reduction; safety and tolerability

Estimated Completion: Not yet announced

Timeline: Recruitment ongoing as of 2026

Publication Medium: Not yet announced

Document Relevance: Ch. 16 (supplements—LDN), Ch. 7 (immune dysfunction—microglial hypothesis)

Younger's laboratory has prior immunology work on LDN in ME/CFS (NCT02965768). While the LIFT trial tests LDN in combination, this study isolates LDN's independent effect and seeks to establish the optimal dose—a fundamental gap in the current evidence base. Most clinicians prescribe 1.5–4.5 mg empirically; systematic dose-finding data could substantially improve clinical practice.

I.7.3 Low-Dose Rapamycin in ME/CFS and Long Covid

Principal Investigator: Multi-site collaboration

Institution: Simmaron Research Institute, Bateman Horne Center, CDC, and Mayo Clinic, United States

Contact/URL: <https://batemanhornecenter.org/promising-clinical-trials/>

Funder: Multi-institutional

Status: Active

Phase: Clinical trial (interventional)

Cohort: ME/CFS and Long Covid patients (specific *n* TBD)

Mechanism/Focus: Rapamycin (sirolimus) is an mTOR inhibitor with immunomodulatory and anti-inflammatory properties. Targets mTOR pathway dysregulation implicated in ME/CFS immune and metabolic abnormalities.

Primary Outcomes: Symptom improvement; immune marker changes; safety and tolerability

Estimated Completion: Not yet announced

Timeline: Study active as of 2025–2026

Publication Medium: Not yet announced

Document Relevance: Ch. 7 (immune dysfunction), Ch. 6 (energy metabolism), Ch. 19 (integrative approaches)

The rapamycin trial is notable for its multi-institutional design (Simmaron, Bateman Horne, CDC, Mayo Clinic), which lends credibility and ensures phenotyping rigour. mTOR pathway dysregulation has been reported in ME/CFS (Chapter 7) and connects immune activation to metabolic dysfunction (Chapter 6). This trial directly tests a mechanistic hypothesis rather than treating symptoms empirically, making it particularly informative regardless of outcome.

I.7.4 Lumbrokinase for ME/CFS and Long Covid

Principal Investigator: David Putrino, PhD

Institution: Abilities Research Center, Mount Sinai Icahn School of Medicine, United States

Contact/URL: <https://solvecfs.org/exploring-current-me-cfs-and-long-covid-clinical-trials->

Funder: Institutional

Status: Recruiting

Phase: Clinical trial (interventional)

Cohort: Adults with Long Covid, post-treatment Lyme disease syndrome, and ME/CFS

Mechanism/Focus: Lumbrokinase is a fibrinolytic enzyme targeting microclot pathology. The microclot hypothesis proposes that persistent fibrin amyloid microclots impair microcirculation, contributing to tissue hypoxia and fatigue.

Primary Outcomes: Fibrinolytic markers; symptom scores; exercise tolerance

Estimated Completion: Not yet announced

Timeline: Recruitment ongoing as of 2026

Publication Medium: Not yet announced

Document Relevance: Ch. 10 (cardiovascular dysfunction), Ch. 19 (integrative approaches)

The microclot hypothesis has generated significant interest since 2021 but lacks interventional trial data. This study directly tests whether fibrinolytic treatment improves outcomes, providing a causal test of the hypothesis. The inclusion of three post-infectious conditions (Long Covid, post-Lyme, ME/CFS) mirrors the Rosetta Stone Study's cross-disease approach, potentially revealing whether microclot pathology is a shared mechanism.

I.7.5 Hydrogen Water for ME/CFS

Principal Investigator: Fred Friedberg, PhD

Institution: Stony Brook University School of Medicine, United States

Contact/URL: <https://solvecfs.org/exploring-current-me-cfs-and-long-covid-clinical-trials->

Funder: Solve ME/CFS Initiative

Status: Recruiting

Phase: Clinical trial, dosing study

Cohort: ME/CFS patients (specific *n* TBD)

Mechanism/Focus: Hydrogen-rich water as an antioxidant intervention. Molecular hydrogen (H₂) selectively scavenges hydroxyl radicals and may reduce oxidative stress and neuroinflammation.

Primary Outcomes: Fatigue severity; stress markers; physical function

Estimated Completion: Not yet announced

Timeline: Recruitment ongoing as of 2026

Publication Medium: Not yet announced

Document Relevance: Ch. 6 (energy metabolism—oxidative stress), Ch. 16 (supplements and nutraceuticals)

This dosing study addresses a practical gap: even if hydrogen water has antioxidant benefits, optimal dosing for ME/CFS has not been established. The oxidative stress hypothesis in ME/CFS (Chapter 6) provides a mechanistic rationale, though the evidence base for molecular hydrogen in any chronic condition remains preliminary. Results will be most informative if they include objective oxidative stress biomarkers alongside subjective symptom measures.

I.7.6 RESTORE-ME: Oxaloacetate for ME/CFS Fatigue

Principal Investigator: Alan Cash, PhD

Institution: Terra Biological LLC, United States (multi-site RCT)

Contact/URL: <https://clinicaltrials.gov/study/NCT05273372>

Registry ID: NCT05273372

Funder: Terra Biological LLC (industry)

Status: Results published (November 2024)

Phase: Phase II, randomised, double-blind, placebo-controlled

Cohort: 82 ME/CFS patients (2,000 mg oxaloacetate vs control daily for 3 months)

Mechanism/Focus: Oxaloacetate (OAA) is a mitochondrial metabolite that supports the citric acid cycle and NAD⁺/NADH ratio. Targets metabolic dysfunction by supplementing a key TCA cycle intermediate.

Primary Outcomes: Fatigue reduced >25% from baseline in OAA group (*p* = 0.0039 vs control); cognitive improvement at day 60 (*p* = 0.034); modest increase in uptime at day 30

Estimated Completion: Completed

Timeline: RCT completed 2024; results published November 2024 in *Frontiers in Neurology*; cognitive follow-up published 2025

Publication Medium: *Frontiers in Neurology* (open access)

Document Relevance: Ch. 6 (energy metabolism—TCA cycle), Ch. 16 (supplements and nutraceuticals)

RESTORE-ME is one of very few completed RCTs showing statistically significant fatigue reduction in ME/CFS. The mechanistic rationale is direct: oxaloacetate is an obligate TCA cycle intermediate, and ME/CFS metabolomic studies have consistently identified TCA cycle disruption (Chapter 6). The 25% fatigue reduction is clinically meaningful, though the modest sample size ($n = 82$) and industry sponsorship warrant independent replication. The cognitive improvement findings strengthen the case that metabolic support can address both physical and cognitive symptoms.

I.7.7 Stellate Ganglion Block for ME/CFS

Principal Investigator: Deborah Duricka, PhD; Lipeng Liu, MD

Institution: Multi-site, United States

Contact/URL: <https://doi.org/10.1080/21641846.2025.2455876>

Funder: Solve ME/CFS Initiative (Ramsay Research Grant)

Status: Pilot study published (February 2025); larger trials needed

Phase: Prospective cohort pilot ($n = 10$)

Cohort: 10 patients meeting both WHO Long Covid and IOM ME/CFS criteria

Mechanism/Focus: Sequential bilateral stellate ganglion blocks (local anaesthetic injection near the cervical sympathetic chain) administered over 3 consecutive weeks. Hypothesised to “reset” sympathetic/parasympathetic balance of the autonomic nervous system, increasing regional blood flow and reducing sympathetic hyperactivation.

Primary Outcomes: Significant improvements in cognition, physical and social functioning, vitality; reduced orthostatic intolerance and POTS symptoms. Cortisol levels did not change.

Estimated Completion: Pilot completed; larger RCT recommended

Timeline: Pilot published February 2025; larger trial planning stage

Publication Medium: *Fatigue: Biomedicine, Health & Behavior* (2025)

Document Relevance: Ch. 10 (cardiovascular/autonomic dysfunction), Ch. 8 (neurological dysfunction), Ch. 19 (integrative approaches)

The stellate ganglion block is a well-established procedure in pain medicine repurposed for autonomic dysfunction. The pilot results are notable for improvement across both autonomic (OI, POTS) and cognitive domains, suggesting a shared upstream mechanism. The “autonomic reset” hypothesis aligns with evidence of sympathetic hyperactivation in ME/CFS (Chapter 10). The very small sample ($n = 10$) limits conclusions, but the effect sizes and the procedure’s established safety profile justify a larger sham-controlled RCT.

I.7.8 Transcutaneous Vagus Nerve Stimulation (tVNS) for Long Covid/ME/CFS

Principal Investigator: Multiple investigators (several parallel studies)

Institution: Multi-site (US and European studies)

Contact/URL: <https://clinicaltrials.gov/study/NCT06585254>

Registry ID: NCT06585254 (US dosing study); additional European trials ongoing

Funder: Multiple (Solve ME/CFS Initiative, institutional)

Status: Recruiting (multiple trials)

Phase: Interventional (parameter optimisation and efficacy)

Cohort: Long Covid and ME/CFS patients fulfilling CFS criteria; prior studies $n = 10\text{--}25$ per trial

Mechanism/Focus: Non-invasive auricular stimulation of the vagus nerve to activate the cholinergic anti-inflammatory pathway (CAP). Targets neuroinflammation, autonomic imbalance, and systemic inflammation. Prior pilot studies showed improvements in cognition, anxiety, depression, sleep, and autonomic scores (COMPASS-31).

Primary Outcomes: Optimal stimulation parameters; health-related quality of life; fatigue severity; autonomic function

Estimated Completion: Varies by trial; results expected 2026–2027

Timeline: Multiple pilot studies published 2024–2025; current trials optimising parameters and assessing efficacy in larger cohorts

Publication Medium: *Frontiers in Neurology*, *PLOS ONE*, and others (prior studies published open access)

Document Relevance: Ch. 8 (neurological dysfunction), Ch. 10 (autonomic dysfunction), Ch. 7 (immune dysfunction—inflammation)

Vagus nerve stimulation represents a compelling intersection of neurology and immunology: the cholinergic anti-inflammatory pathway provides a mechanism through which neural stimulation can modulate systemic inflammation. The consistency of improvements across multiple small pilot studies (cognition, autonomic function, sleep) is encouraging, though no large RCT has yet been completed. The non-invasive nature, low side-effect profile, and consumer device availability (e.g., Nurosym) make tVNS a practical intervention if efficacy is confirmed. The current parameter-optimisation trials are a necessary step before definitive efficacy studies.

I.7.9 Masitinib for Severe Mast Cell Activation Syndrome

Principal Investigator: Multiple investigators

Institution: AB Science (sponsor), multi-site

Contact/URL: <https://clinicaltrials.gov/study/NCT05449444>

Registry ID: NCT05449444

Funder: AB Science (industry)

Status: Phase 2 (active)

Phase: Phase 2 clinical trial

Cohort: Patients with severe mast cell activation syndrome (MCAS)

Mechanism/Focus: Masitinib is a tyrosine kinase inhibitor that targets mast cell activity directly, unlike antihistamines that only address downstream mediator release. MCAS is identified in an estimated 50% of ME/CFS patients by some specialists.

Primary Outcomes: MCAS symptom severity; safety and tolerability

Estimated Completion: Not yet announced

Timeline: Trial active as of 2025–2026

Publication Medium: Not yet announced

Document Relevance: Ch. 7 (immune dysfunction—mast cells), Ch. 19 (integrative approaches)

Mast cell activation has emerged as a significant comorbidity in ME/CFS subsets, with some clinicians reporting MCAS in up to half of their ME/CFS patients. A 2026 cromolyn sodium case series from Dutch and Johns Hopkins investigators showed improvement in ME/CFS-related symptoms alongside MCAS management. Masitinib's upstream mechanism (direct tyrosine kinase inhibition rather than antihistamine blockade) could provide more complete mast cell stabilisation. If effective, this trial could open a treatment pathway for the MCAS subset of ME/CFS patients who respond poorly to conventional antihistamine regimens.

I.7.10 Cornell NAC–Glutathione Brain Study

Principal Investigator: Dikoma Shungu, PhD

Institution: Weill Cornell Medical College, United States

Contact/URL: <https://clinicaltrials.gov/study/NCT04542161>

Registry ID: NCT04542161

Funder: NINDS (National Institute of Neurological Disorders and Stroke)

Status: Recruiting (Phase 2)

Phase: Phase 2, double-blind, placebo-controlled, randomised

Cohort: 60 participants (20 per arm: 0 mg / 900 mg / 3600 mg daily NAC), ages 21–60, baseline brain GSH at or below predefined cutoff, primary ME/CFS diagnosis

Mechanism/Focus: Tests N-acetylcysteine (NAC) as a glutathione (GSH) precursor to restore cortical GSH reserves depleted by oxidative stress. Uses magnetic resonance spectroscopy (MRS) to measure brain GSH levels as a direct target engagement biomarker. Three-arm dose-response design.

Primary Outcomes: Brain GSH levels (MRS); plasma oxidative stress markers

Estimated Completion: ~2026

Timeline: Recruitment ongoing

Publication Medium: Not yet announced

Document Relevance: Ch. 6 (energy metabolism—oxidative stress), Ch. 22 (mechanistic studies)

This trial is notable for using MRS as both a mechanistic measurement and treatment-response biomarker in a single tool. If NAC restores brain GSH levels and correlates with symptom

improvement, it would establish oxidative stress as a druggable target in ME/CFS and validate a non-invasive brain biomarker for treatment monitoring. The three-arm dose-response design addresses the fundamental question of whether standard supplement doses (900 mg) achieve meaningful CNS penetration.

I.7.11 NSU Directed Probiotics for ME/CFS

Principal Investigator: Nancy Klimas, MD

Institution: Nova Southeastern University, Institute for Neuro-Immune Medicine, United States

Contact/URL: <https://clinicaltrials.gov/study/NCT06211062>

Registry ID: NCT06211062

Funder: Institutional

Status: Recruiting (Phase 2)

Phase: Phase 2, randomised, placebo-controlled

Cohort: 100 participants (25 per arm × 4 arms: ME/CFS with/without IBS × active/placebo), ages 45–70, Canadian Consensus Criteria

Mechanism/Focus: Tests i3.1 probiotic (Floradapt Intensive GI) to reduce GI inflammation, normalise gut–brain axis, and reset microbiome. Four-arm design allows interaction analysis between IBS comorbidity and treatment response.

Primary Outcomes: GI inflammation markers; IBS severity score; ME/CFS global function; assessed at 8 and 12 weeks

Estimated Completion: ~2026

Timeline: Recruitment ongoing

Publication Medium: Not yet announced

Document Relevance: Ch. 11 (gut microbiome—primary), Ch. 7 (immune dysfunction—gut–immune axis)

This is the first ME/CFS-specific probiotic RCT with IBS stratification. The Klimas group's neuro-immune medicine expertise and the four-arm design (separating ME/CFS-only from ME/CFS+IBS) could determine whether gut-targeted interventions benefit all ME/CFS patients or specifically those with GI comorbidity—a distinction with direct clinical implications for the microbiome hypothesis discussed in Chapter 11.

I.7.12 ADDRESS-LC (Bezisterim for Long Covid Neurocognition)

Principal Investigator: Multi-site (BioVie Inc.)

Institution: Multi-centre, United States (DoD-funded)

Contact/URL: <https://clinicaltrials.gov/study/NCT06847191>

Registry ID: NCT06847191

Funder: Department of Defense (US)

Status: Recruiting (first patient enrolled May 2025)

Phase: Phase 2, multi-centre, double-blind, RCT

Cohort: 200 adults with Long Covid, enriched for cognitive impairment and fatigue, symptoms ≥ 3 months

Mechanism/Focus: Bezisterim (NE3107) is an orally bioavailable, blood–brain barrier-permeable insulin sensitiser and selective NF- κ B/ERK modulator. Blocks TNF- α and neuroinflammation without global immunosuppression. Targets the neuroinflammation hypothesis for brain fog. Same drug being explored in Alzheimer’s and Parkinson’s.

Primary Outcomes: Cogstate Cognition battery (cognitive performance); secondary: fatigue

Estimated Completion: Data expected H1 2026

Timeline: 84-day treatment period

Publication Medium: Not yet announced

Document Relevance: Ch. 7 (immune dysfunction—neuroinflammation), Ch. 22 (mechanistic studies—Long Covid overlap)

ADDRESS-LC is notable for targeting neuroinflammation via a mechanism distinct from LDN: selective NF- κ B modulation rather than glial cell modulation. The blood–brain barrier permeability and dual insulin-sensitising/anti-inflammatory action address two pathophysiological axes simultaneously. Cross-disease application (Alzheimer’s, Parkinson’s, Long Covid) could accelerate regulatory pathways and provide comparative data on shared neuroinflammatory mechanisms.

1.7.13 LC-REVITALIZE (Upadacitinib + Pirfenidone)

Principal Investigator: Douglas Fraser, MD PhD

Institution: Western University, London, Ontario, Canada; Schmidt Initiative for Long COVID (SILC); multi-national

Contact/URL: <https://clinicaltrials.gov/study/NCT06928272>

Registry ID: NCT06928272

Funder: Schmidt Initiative for Long COVID (SILC)

Status: Recruiting (Phase 3)

Phase: Phase 3, double-blind, placebo-controlled, multi-arm platform

Cohort: ~348 adults with Long Covid (prior confirmed SARS-CoV-2, symptoms ≥ 3 months); sites in Brazil, Canada, Italy, Uganda, USA, Zambia

Mechanism/Focus: Repurposed drug platform trial. Upadacitinib (JAK1 inhibitor, approved for rheumatoid arthritis) and pirfenidone (anti-fibrotic, approved for lung disease) identified via AI proteomics screen of 5,400 blood proteins from 1,028 participants.

Primary Outcomes: Five symptom domains: fatigue, breathlessness, cognition, musculoskeletal pain, circulation

Estimated Completion: ~2027

Timeline: Recruitment ongoing across 6 countries

Publication Medium: Not yet announced

Document Relevance: Ch. 7 (immune dysfunction—JAK pathway), Ch. 13 (integrative models), Ch. 22 (mechanistic studies—Long Covid overlap)

LC-REVITALIZE is the first Long Covid treatment trial to use AI-driven proteomics for drug selection, screening 5,400 proteins to identify candidate interventions. The JAK1 inhibitor arm complements the RECOVER-TLC baricitinib trial (Section I.6.1), testing a more selective JAK inhibitor. The multi-national platform design across six countries enables geographic and genetic diversity rarely achieved in ME/CFS-adjacent trials. If positive, the AI proteomics drug-selection methodology could be applied directly to ME/CFS cohorts.

I.7.14 Viral Persistence Trials (Paxlovid/STOP-PASC)

Principal Investigator: Multiple (NIH-funded)

Institution: Multi-site across the United States

Contact/URL: <https://clinicaltrials.gov/study/NCT05576662>

Registry ID: NCT05576662 (STOP-PASC); PAX LC (separate trial)

Funder: NIH

Status: Completed; results published 2025

Phase: Phase 2, randomised, double-blind, placebo-controlled

Cohort: Adults with established Long Covid (STOP-PASC and PAX LC trials)

Mechanism/Focus: Nirmatrelvir/ritonavir (Paxlovid) for 15 days to test whether antiviral treatment targeting SARS-CoV-2 viral persistence improves Long Covid symptoms. Both STOP-PASC and PAX LC trials showed **no therapeutic benefit**, despite the viral persistence hypothesis.

Primary Outcomes: No significant improvement in Long Covid symptoms vs placebo in either trial

Estimated Completion: Completed

Timeline: Results from STOP-PASC (systems immunology analysis) published December 2025; PAX LC results published in *The Lancet Infectious Diseases* (2025)

Publication Medium: *The Lancet Infectious Diseases*; *medRxiv* (systems immunology analysis)

Document Relevance: Ch. 7 (immune dysfunction), Ch. 14 §14.17 (cross-disease), Ch. 24 (controversies)

The negative results from STOP-PASC and PAX LC are as informative as positive findings would have been. If SARS-CoV-2 viral persistence were the primary driver of Long Covid symptoms, a 15-day course of a potent antiviral should have produced measurable improvement. The failure to do so suggests either that viral persistence is not the dominant mechanism in established Long Covid, that the treatment duration or timing was insufficient, or that downstream consequences of initial infection (immune dysregulation, autoimmunity, microbiome disruption) persist independently of ongoing viral replication. This has direct implications for ME/CFS, where post-infectious mechanisms similarly outlast the triggering infection.

I.7.15 CHIIME (Chronic Infections and Inflammation in ME/CFS)

Principal Investigator: UCSF / PolyBio Research Foundation network (LIINC collaborative); Dr. John Chia (Enterovirus Medical Research Center) as key partner

Institution: University of California San Francisco, United States

Contact/URL: <https://clinicaltrials.gov/study/NCT07227441>

Registry ID: NCT07227441

Funder: PolyBio Research Foundation

Status: Recruiting (start date January 2026)

Phase: Observational, prospective, longitudinal

Cohort: ME/CFS patients with pre-2019 onset only (excludes Long Covid onset to avoid confounding)

Mechanism/Focus: Investigates viral persistence (particularly enterovirus tissue persistence in gut, muscle, brain), T-cell neuroinflammation, and longitudinal biological signatures. Gut tissue collected from a subset via biopsy to search for enterovirus RNA/protein. Uses whole-body PET imaging and single-nuclei RNA sequencing.

Primary Outcomes: Longitudinal biomarker trajectories; enterovirus persistence confirmation; neuroimmune phenotyping

Estimated Completion: September 2030

Timeline: Multi-year longitudinal follow-up

Publication Medium: Not yet announced

Document Relevance: Ch. 7 (immune dysfunction—viral persistence), Ch. 11 (gut microbiome), Ch. 13 (integrative models), Ch. 22 (mechanistic studies)

CHIIME represents a paradigm shift from serology-based viral persistence research to direct tissue-level detection. By collecting gut, muscle, and CNS-adjacent tissue, this study can directly test whether enterovirus RNA and protein persist in tissues of ME/CFS patients—moving beyond the indirect evidence that has characterised viral persistence research for decades. The pre-2019 onset criterion ensures that findings apply to classical ME/CFS rather than post-COVID presentations, addressing a critical gap in the field.

I.8 Virology and Post-Infectious Mechanisms

I.8.1 Herpesvirus Reactivation and Anti-dUTPase Antibodies

Principal Investigator: María Palomo and collaborators

Institution: Multi-centre (Spain / USA)

Contact/URL: <https://doi.org/10.1002/jmv.70769>

Funder: Institutional

Status: Published 2026

Phase: Observational (case-control)

Cohort: ME/CFS patients + healthy controls

Mechanism/Focus: Measured antibodies to EBV, HHV-6, and VZV, plus anti-dUTPase IgG (a marker of active herpesvirus replication). 72.5% of ME/CFS patients simultaneously co-expressed antibodies to multiple herpesviruses versus 31% of controls. Heightened herpesvirus antibody levels clustered with moderate-to-severe fatigue.

Primary Outcomes: Multi-herpesvirus co-reactivation as hallmark of post-infectious ME/CFS; anti-dUTPase IgG as fatigue-associated marker

Estimated Completion: Published

Publication Medium: *Journal of Medical Virology*

Document Relevance: Ch. 7 (immune dysfunction), Ch. 9 (infection and triggers), Ch. 20 (biomarker research)

The simultaneous co-reactivation of three herpesviruses in over 70% of patients suggests systemic immune surveillance failure rather than reactivation of a single pathogen [341]. The anti-dUTPase antibody is mechanistically interesting because dUTPase is an enzyme conserved across herpesviruses that can directly activate innate immune signalling. If validated as a stratification marker, it could identify a “viral reactivation” subtype amenable to antiviral or immunomodulatory therapy.

I.8.2 Post-IM Longitudinal Cohort: Seven-Year Follow-Up

Principal Investigator: Ben Z. Katz, MD

Institution: Northwestern University / multi-site (USA)

Contact/URL: <https://doi.org/10.3389/fmed.2026.1676628>

Funder: NIH

Status: Published 2026

Phase: Observational, prospective longitudinal cohort

Cohort: 4,501 college students enrolled before developing infectious mononucleosis (IM); followed for 7 years

Mechanism/Focus: Uniquely prospective design: baseline data collected at least 6 weeks before IM onset. Tracks natural history from pre-infection through ME/CFS development, enabling identification of pre-existing risk factors.

Primary Outcomes: ME/CFS incidence: 13% at 6 months, declining to ~4% at 24 months post-IM. Risk factor identification at 7-year endpoint

Estimated Completion: Published

Publication Medium: *Frontiers in Medicine*

Document Relevance: Ch. 9 (infection and triggers), Ch. 23 (epidemiology), Ch. 14 §14.17 (post-viral overlap)

This is one of the few truly prospective studies in ME/CFS, with pre-infection baseline data that enables causal inference about risk factors—a design strength shared with the DecodeME genetic study (Section I.2.1). The declining incidence from 13% to 4% over two years suggests spontaneous recovery in most post-IM ME/CFS cases, but the persistent 4% represents a “locked-in” subset of particular clinical and research interest [847].

I.8.3 RECOVER ME/CFS Incidence Study

Principal Investigator: RECOVER Consortium

Institution: NIH multi-site (USA)

Contact/URL: <https://doi.org/10.1007/s11606-024-09290-9>

Funder: NIH RECOVER Initiative

Status: Published 2025

Phase: Observational (adult cohort)

Cohort: Large-scale RECOVER-Adult observational study

Mechanism/Focus: Determined incidence and prevalence of ME/CFS following SARS-CoV-2 infection. Applies established diagnostic criteria to the largest prospective post-COVID cohort.

Primary Outcomes: Confirmed that ME/CFS incidence increases following SARS-CoV-2 infection; provides population-level estimates

Estimated Completion: Published

Publication Medium: *Journal of General Internal Medicine*

Document Relevance: Ch. 9 (infection and triggers), Ch. 23 (epidemiology), Ch. 14 §14.17

This study provides the strongest epidemiological evidence to date that SARS-CoV-2 infection increases ME/CFS incidence, confirming a pattern previously observed with EBV, Ross River virus, and *Coxiella burnetii* [158]. The RECOVER infrastructure's scale enables subgroup analyses by demographics, infection severity, and vaccination status that smaller cohorts cannot support.

I.9 Immune Profiling and T Cell Research

I.9.1 CD8+ T Cell Exhaustion Atlas

Principal Investigator: Multiple groups (NIH intramural)

Institution: NIH / multi-centre

Contact/URL: <https://doi.org/10.1073/pnas.2415119121>

Funder: NIH intramural

Status: Published 2025

Phase: Observational (scRNA-seq atlas)

Cohort: 28 ME/CFS patients + 30 sedentary controls; 336,269 T lymphoid cells analysed

Mechanism/Focus: Single-cell transcriptomics of CD8+ T cells at baseline and after symptom provocation (exercise challenge). Identified transcriptional reprogramming toward exhaustion phenotypes, with altered effector, memory, and regulatory T cell subsets.

Primary Outcomes: CD8+ T cells in ME/CFS show exhaustion-associated gene expression; exercise provocation amplifies the dysregulation

Estimated Completion: Published

Publication Medium: *Proceedings of the National Academy of Sciences*

Document Relevance: Ch. 7 (immune dysfunction), Ch. 6 (energy metabolism—immune cell energetics), Ch. 22 (mechanistic studies)

T cell exhaustion was previously studied mainly in cancer and chronic viral infections. Its identification in ME/CFS opens a therapeutic avenue: checkpoint inhibitor-like approaches that reverse exhaustion might restore immune surveillance and reduce symptom burden [326]. The exercise provocation design is particularly valuable, as it captures the dynamic immune dysregulation underlying post-exertional malaise rather than just resting-state differences. The finding that monocyte fractions correlate with disease severity suggests potential for severity stratification.

I.9.2 Single-Cell Immune Remodelling in Long COVID–ME/CFS

Principal Investigator: Shokrollah Elahi and collaborators

Institution: University of Alberta, Canada

Contact/URL: Science for ME discussion thread

Funder: Institutional / CIHR

Status: Published 2026

Phase: Observational (scRNA-seq)

Cohort: Female long COVID–ME/CFS patients (12 months post-acute infection) versus recovered individuals

Mechanism/Focus: scRNA-seq of PBMCs examining monocyte, NK cell, and T cell compartments. Identified persistent immune remodelling 12 months after infection in those who developed ME/CFS but not in those who recovered.

Primary Outcomes: Distinct monocyte polarisation, NK cell dysfunction, and T cell exhaustion patterns specific to ME/CFS development after COVID-19

Estimated Completion: Published

Publication Medium: *Nature Communications*

Document Relevance: Ch. 7 (immune dysfunction), Ch. 14 §14.17 (long COVID comparison)

This study complements the NIH T cell atlas (Section I.9.1) by examining the transition from acute infection to chronic disease. The comparison of ME/CFS developers versus recoverers at the same time point (12 months) provides a natural experiment for identifying immune features that distinguish pathological from physiological post-infection states [327].

I.9.3 IgG Immune Complexes Disrupting Cellular Energetics

Principal Investigator: Bhupesh K. Prusty (senior), Zhihang Liu (first author)

Institution: Multi-centre

Funder: Institutional

Status: Published February 2026

Phase: Observational (in vitro)

Cohort: ME/CFS (n=39–40), post-COVID ME/CFS (n=15–16), healthy controls (n=39–41), MS controls (n=11–20), systemic sclerosis (n=21)

Mechanism/Focus: Isolated IgG complexes from ME/CFS patient sera and applied them to human umbilical vein endothelial cells (HUVECs). Demonstrated that ME/CFS-derived IgG induces mitochondrial fragmentation while maintaining ATP production (stress adaptation rather than energy collapse), triggers IL-1 β secretion, and produces disease-specific proteomic signatures: post-COVID IgG enriched in hemostasis/clotting pathways, classic ME/CFS in extracellular matrix remodelling pathways.

Primary Outcomes: IgG from ME/CFS patients causes mitochondrial fragmentation in endothelial cells; effect predominantly in female patients; maintained spare respiratory capacity with glycolytic compensation

Estimated Completion: Published

Publication Medium: *Brain, Behavior, and Immunity – Health*

Document Relevance: Ch. 6 (energy metabolism), Ch. 7 (immune dysfunction—autoantibodies), Ch. 10 (endothelial dysfunction), Ch. 13 (integrative models)

This is among the strongest “transfer experiment” results in ME/CFS: applying patient-derived IgG to healthy endothelial cells recapitulates mitochondrial disruption and inflammatory activation, implicating humoral immune factors as causal rather than epiphenomenal [103]. If replicated with purified IgG subfractions, it could identify specific autoantibody targets and converge with the daratumumab (Section I.4.3) and immunoadsorption (Section I.4.1) therapeutic approaches.

I.10 Cardiovascular, Autonomic, and Vascular Research

I.10.1 MCAM Multi-Site Autonomic Dysfunction Study

Principal Investigator: Elizabeth Unger and collaborators

Institution: CDC / multi-site (USA)

Contact/URL: <https://doi.org/10.3390/jcm14176269>

Funder: CDC

Status: Published 2025

Phase: Observational (multi-site clinical assessment)

Cohort: ME/CFS patients from the MCAM (Multi-Site Clinical Assessment of ME/CFS) programme

Mechanism/Focus: Characterised autonomic dysfunction using COMPASS-31 scores and the NASA lean test. Demonstrated high prevalence of autonomic symptoms across ME/CFS cohorts regardless of recruitment site.

Primary Outcomes: Autonomic dysfunction symptoms are pervasive in ME/CFS; COMPASS-31 scores significantly elevated versus controls

Estimated Completion: Published

Publication Medium: *Journal of Clinical Medicine*

Document Relevance: Ch. 10 (cardiovascular), Ch. 8 (neurological dysfunction—autonomic)

The MCAM study's multi-site design strengthens generalisability: autonomic dysfunction is not an artefact of specialist referral patterns but a consistent feature across diverse clinical settings [462]. The NASA lean test used here is simpler than head-up tilt, making it a practical screening tool for primary care.

I.10.2 Small Fibre Neuropathy in ME/CFS and Post-COVID

Principal Investigator: Naia Azcue and collaborators

Institution: Multi-centre (Spain)

Contact/URL: <https://doi.org/10.1111/ene.70016>

Funder: Institutional

Status: Published 2025

Phase: Observational (case-control)

Cohort: ME/CFS patients, post-COVID patients, and healthy controls

Mechanism/Focus: Assessed small fibre neuropathy using electrochemical skin conductance, nerve reaction times to temperature stimuli, and corneal confocal microscopy. Both ME/CFS and post-COVID patients showed significantly higher autonomic and neuropathic symptom burden than controls.

Primary Outcomes: SFN features present in both ME/CFS and post-COVID; corneal nerve fibre density reduced

Estimated Completion: Published

Publication Medium: *European Journal of Neurology*

Document Relevance: Ch. 8 (neurological dysfunction), Ch. 10 (cardiovascular—perfusion), Ch. 14 §14.17

Small fibre neuropathy provides an objective, quantifiable marker for a symptom—neuropathic pain and dysautonomia—that is otherwise self-reported [461]. The corneal confocal microscopy approach is non-invasive and could serve as a bedside diagnostic. The shared SFN phenotype between ME/CFS and post-COVID strengthens the case for common neurovascular pathology.

I.10.3 Microvascular Remodelling and Endothelial Dysfunction

Principal Investigator: Multiple groups

Institution: Multi-centre (Europe)

Contact/URL: <https://doi.org/10.64898/2026.01.22.26344661>

Funder: Institutional

Status: Preprint January 2026

Phase: Observational (case-control)

Cohort: Post-COVID and ME/CFS patients versus healthy controls

Mechanism/Focus: Used retinal vessel analysis as a non-invasive measure of systemic microvascular health. Identified reduced venular flicker-induced dilation in patients, indicating ongoing endothelial dysfunction even in clinically stable individuals.

Primary Outcomes: Endothelial dysfunction detectable via retinal imaging; reduced venular reactivity in ME/CFS and post-COVID

Estimated Completion: Preprint published; peer review pending

Publication Medium: medRxiv

Document Relevance: Ch. 10 (cardiovascular), Ch. 13 (integrative models)

Retinal vessel analysis offers a window into systemic microvascular health without invasive procedures [460]. The persistent endothelial dysfunction in clinically stable patients suggests ongoing vascular injury that may underlie fatigue and cognitive symptoms even when patients report partial recovery. This complements the microclot findings [292] and the coagulation proteomics data [848].

I.10.4 POTS Autonomic Profiling Across Aetiologies

Principal Investigator: Multiple groups

Institution: Multi-centre

Status: Published 2025

Phase: Observational (comparative)

Cohort: POTS patients from syncope, CFS, and post-COVID-19 populations

Mechanism/Focus: Identified distinct autonomic profiles: syncope-related POTS showed baroreceptor dysfunction and sympathetic predominance, whereas CFS-related POTS was characterised by parasympathetic impairment and impaired short-term baroreflex regulation.

Primary Outcomes: CFS-related POTS has a distinct autonomic signature from syncope-related and post-COVID POTS

Estimated Completion: Published

Document Relevance: Ch. 10 (cardiovascular), Ch. 8 (neurological dysfunction—autonomic)

The distinction between CFS-related and syncope-related POTS autonomic profiles has therapeutic implications: parasympathetic impairment in CFS-related POTS suggests vagal tone-targeting interventions (e.g., tVNS, Section I.7.8) may be more appropriate than the beta-blockade used for hyperadrenergic POTS [849].

I.11 Exercise Physiology and Muscle Biology

I.11.1 Largest Two-Day CPET Study

Principal Investigator: Multiple groups

Institution: Multi-centre (USA)

Contact/URL: <https://doi.org/10.1186/s12967-024-05410-5>

Funder: Institutional

Status: Published 2024

Phase: Observational (physiological testing)

Cohort: Largest 2-day CPET cohort in ME/CFS to date

Mechanism/Focus: Two-day cardiopulmonary exercise testing to objectively measure post-exertional malaise. Significant reductions in VO_2 and workload at the ventilatory anaerobic threshold (VAT) on day 2 in ME/CFS versus controls. Implicates autonomic dysregulation of blood flow and oxygen delivery for energy metabolism.

Primary Outcomes: Impaired recovery after exertional stressor; cardiac, pulmonary, and metabolic contributions to exertion intolerance; larger effect sizes at VAT than peak

Estimated Completion: Published

Publication Medium: *Journal of Translational Medicine*

Document Relevance: Ch. 6 (energy metabolism), Ch. 10 (cardiovascular), Ch. 20 (biomarker research—2-day CPET as objective PEM marker)

The 2-day CPET protocol remains the gold standard for objectively demonstrating PEM. This largest study to date substantiates that the day-2 decrement is reproducible across diverse ME/CFS cohorts [1]. The finding that cardiac, pulmonary, and metabolic factors all contribute to exertion intolerance supports the multi-system model in Ch. 13 rather than any single-organ explanation.

I.11.2 Skeletal Muscle Properties in Long COVID and ME/CFS

Principal Investigator: Multiple groups

Institution: Multi-centre (Netherlands / Europe)

Contact/URL: <https://doi.org/10.1101/2025.05.02.25326885>

Funder: Institutional

Status: Preprint May 2025

Phase: Observational (muscle biopsy)

Cohort: Long COVID and ME/CFS patients versus controls

Mechanism/Focus: Muscle biopsies analysed for mitochondrial markers, WASF3 protein, ER stress markers. Found elevated WASF3 and ER stress with decreased mitochondrial Complex IV subunits. Critically, muscle abnormalities differed from those seen in bed rest deconditioning.

Primary Outcomes: ME/CFS muscle pathology is distinct from deconditioning; WASF3 elevation confirmed in skeletal muscle tissue

Estimated Completion: Preprint published; peer review pending

Publication Medium: medRxiv

Document Relevance: Ch. 6 (energy metabolism—WASF3), Ch. 17 (lifestyle interventions—exercise contraindications)

This study provides crucial evidence against the deconditioning hypothesis: if ME/CFS fatigue were due to simple disuse, muscle changes should resemble bed rest patterns [294]. The distinct pathology (WASF3 elevation, mitochondrial complex loss) aligns with the NIH WASF3 findings [2] and supports a disease-specific metabolic myopathy rather than secondary deconditioning.

I.12 Microbiome and Gut–Brain Axis

I.12.1 JAX AI-Integrated Gut Microbiome Diagnostic

Principal Investigator: Jackson Laboratory and Duke University collaborators

Institution: JAX / Duke University (USA)

Contact/URL: <https://www.jax.org/news-and-insights/2025/july/gut-microbiome-may-predict-in>

Funder: Institutional / NIH

Status: Published July 2025

Phase: Diagnostic development (AI-driven)

Cohort: 249 individuals

Mechanism/Focus: Applied an AI platform to stool, blood, and routine lab data to identify disease-specific biomarkers. Achieved 90% accuracy in distinguishing ME/CFS from healthy controls using microbiome and metabolite features.

Primary Outcomes: 90% diagnostic accuracy; multimodal data (stool + blood + labs) outperforms any single data type

Estimated Completion: Published

Document Relevance: Ch. 11 (gut microbiome), Ch. 20 (biomarker research), Ch. 25 (translational findings)

The 90% accuracy is the highest reported for any ME/CFS biomarker panel to date, though it awaits independent validation in a blinded, multi-site cohort [478]. The multimodal approach (combining stool microbiome with blood and clinical data) may explain the performance gain over single-modality studies. This directly informs the diagnostic algorithm discussed in Ch. 20.

I.12.2 Gut Microbial Composition Differences in CFS

Principal Investigator: Multiple groups

Institution: Multi-centre

Contact/URL: <https://doi.org/10.1038/s41598-025-16438-y>

Status: Published 2025

Phase: Observational (case-control)

Cohort: CFS patients versus healthy controls

Mechanism/Focus: 16S rRNA sequencing of gut microbiota. Found reduced microbial diversity, depletion of anti-inflammatory taxa (*Faecalibacterium prausnitzii*, *Bifidobacterium*), and enrichment of pro-inflammatory *Clostridium* species in ME/CFS.

Primary Outcomes: Significant between-group differences in gut microbial composition

Estimated Completion: Published

Publication Medium: *Scientific Reports*

Document Relevance: Ch. 11 (gut microbiome), Ch. 7 (immune dysfunction—gut-mediated inflammation)

The depletion of *F. prausnitzii* (a major butyrate producer) is particularly notable because butyrate maintains intestinal barrier integrity. Its loss could contribute to the intestinal permeability (“leaky gut”) reported in ME/CFS, creating a pathway from microbiome dysbiosis to systemic immune activation [477].

I.13 Endocrine and Metabolic Profiling

I.13.1 Sex-Specific Steroid Hormone Profiling

Principal Investigator: Multiple groups

Institution: Multi-centre

Contact/URL: <https://doi.org/10.1007/s40618-024-02334-1>

Funder: Institutional

Status: Published 2024

Phase: Observational (cross-sectional)

Cohort: ME/CFS patients + healthy controls

Mechanism/Focus: UHPLC-MS/MS analysis of circulating steroid hormones: mineralocorticoids (aldosterone), glucocorticoids (cortisol, corticosterone, 11-deoxycortisol, cortisone), androgens (androstenedione, testosterone), and progestins (progesterone, 17 α -hydroxyprogesterone). Found sex-based differences in hormone profiles.

Primary Outcomes: Sex-specific steroid hormone dysregulation in ME/CFS; reinforces need for sex-stratified analyses

Estimated Completion: Published

Publication Medium: *Journal of Endocrinological Investigation*

Document Relevance: Ch. 8 (neuroendocrine dysfunction), Ch. 23 (epidemiology—sex differences)

The sex-based differences in steroid profiles may partly explain the female predominance in ME/CFS (~3:1 female-to-male ratio) [438]. The use of mass spectrometry (rather than immunoassay) provides superior specificity for closely related steroid metabolites, reducing cross-reactivity artefacts that have confounded earlier HPA axis studies.

I.14 Kynurenine Pathway

I.14.1 OMF Kynurenine Supplementation Trial

Principal Investigator: Open Medicine Foundation researchers

Institution: OMF-funded site

Contact/URL: <https://www.omf.ngo/kynurenine-trial-in-me-cfs/>

Funder: Open Medicine Foundation

Status: Recruiting / active

Phase: Interventional (RCT, crossover)

Cohort: ME/CFS patients

Mechanism/Focus: Randomised to kynurenine or placebo for 3 months followed by crossover. Tests whether exogenous kynurenine supplementation can correct tryptophan metabolism disturbances reported in ME/CFS. The kynurenine pathway mediates immune response and neuroinflammation through metabolites like quinolinic acid and kynurenic acid.

Primary Outcomes: Fatigue, cognitive function, immune markers; kynurenine/tryptophan ratio changes

Estimated Completion: TBD

Document Relevance: Ch. 6 (energy metabolism—NAD⁺ synthesis via kynurenine pathway), Ch. 8 (neurological dysfunction—neuroinflammation), Ch. 16 (supplements)

The kynurenine pathway sits at the intersection of immune activation and energy metabolism: IDO-driven tryptophan diversion reduces serotonin availability while generating both neuroprotective (kynurenic acid) and neurotoxic (quinolinic acid) metabolites [850]. If kynurenine supplementation improves symptoms, it would confirm that tryptophan diversion is a treatable metabolic bottleneck in ME/CFS.

I.15 Comorbid Conditions: EDS–MCAS–ME/CFS Triad

I.15.1 EDS–MCAS Genetic and Pathophysiological Basis

Principal Investigator: Multiple groups

Institution: Multi-centre (international)

Contact/URL: PMID 41554340 (2026 review); PMID 39451569 (2024 genetics)

Funder: Institutional

Status: Published 2024–2026

Phase: Review and genetic analysis

Cohort: hEDS patients + controls (genetics: $n \approx 250$)

Mechanism/Focus: Two convergent lines of research: (1) a 2026 review examining pathophysiological and clinical links between EDS and MCAS, highlighting bidirectional

fibroblast–mast cell interactions in the extracellular matrix; (2) a 2024 genetic study identifying variants in MT-CYB, HTT, MUC3A, HLA-B, and HLA-DRB1 implicated in hEDS and mast cell hypersensitivity (72.2% of hEDS cohort vs 14.2% controls).

Primary Outcomes: Genetic basis for the EDS–MCAS overlap; pathophysiological framework for the clinical triad

Estimated Completion: Published

Document Relevance: Ch. 7 (immune dysfunction—mast cells), Ch. 10 (cardiovascular—connective tissue), Ch. 14 §14.17 (comorbidity patterns)

The EDS–MCAS–ME/CFS triad is one of the most clinically recognisable comorbidity patterns, yet its biological basis has been poorly understood [851, 852]. The fibroblast–mast cell interaction framework provides a mechanistic link: abnormal collagen (EDS) alters the extracellular matrix, which modulates mast cell behaviour (MCAS), which drives systemic immune activation (ME/CFS). The HLA associations suggest an autoimmune component that connects to the broader autoantibody research in Sections I.4.1–I.4.3.

I.16 Conferences and Funding Initiatives

I.16.1 International ME/CFS Conference 2026 (Berlin)

Organiser: ME/CFS Research Foundation

Location: Berlin, Germany

Dates: 7–8 May 2026

Contact/URL: <https://mecfs-research.org/en/news-conference2026/>

Focus: Day 1: disease mechanisms (PEM, pain, cognitive dysfunction, circulatory disorders, dysautonomia). Day 2: clinical trial results and treatment data. Aimed at the medical and research community.

Document Relevance: Multiple chapters; unpublished data presented here may update several registry entries

This conference is the primary venue for new ME/CFS data presentation in 2026 [853]. Several registry entries (BC007, HBOT, LDN trials) may present interim or final results. The registry should be updated after the conference.

I.16.2 ME/CFS Research Foundation 2026 Funding Strategy

Organiser: ME/CFS Research Foundation (Germany)

Contact/URL: <https://mecfs-research.org/en/fundingstrategy2026/>

Focus: 2026 funding priorities: autoimmunity, immune dysregulation, metabolic disorders, inflammation, vascular dysfunction, and nervous system dysfunction as causal factors in ME/CFS. Supports projects addressing central symptoms (PEM, pain, cognitive dysfunction, circulatory disorders, dysautonomia).

Document Relevance: Signals research direction for the field; funded projects will appear as future registry entries

I.17 Digital Health and Wearable Technology

I.17.1 Long Covid Wearable Device Study

Principal Investigator: Julia Moore Vogel, PhD

Institution: Scripps Research Institute, United States

Contact/URL: <https://solvecfs.org/exploring-current-me-cfs-and-long-covid-clinical-trials->

Funder: Institutional

Status: Recruiting

Phase: Observational, digital health

Cohort: Adults with Long Covid, ME/CFS, or POTS

Mechanism/Focus: Evaluates whether consumer wearable devices (e.g., Fitbit, Garmin) can support activity pacing, symptom management, and overall quality of life. Collects continuous physiological data (heart rate, activity, sleep) to quantify PEM triggers.

Primary Outcomes: Pacing adherence; symptom management effectiveness; quality of life; PEM episode frequency

Estimated Completion: Not yet announced

Timeline: Recruitment ongoing as of 2026

Publication Medium: Not yet announced

Document Relevance: Ch. 17 (lifestyle interventions—pacing), Ch. 10 (cardiovascular/autonomic monitoring)

While not a biomarker or therapeutic study, this research addresses a critical practical question for ME/CFS management. Activity pacing is the primary non-pharmacological intervention (Chapter 17), yet objective tools to support pacing remain poorly validated. If wearable-derived metrics (heart rate variability, activity thresholds) can reliably predict PEM onset, this could transform day-to-day management for patients.

I.18 Results Expected in 2026–2027

Several studies in this registry are expected to report results in the near term. Table [I.1](#) highlights those with the highest potential impact on ME/CFS understanding and treatment.

Recently published results to monitor for follow-up studies. Multiple registry entries have reported results that may generate replication or extension studies in 2026–2027:

- **RESTORE-ME** (oxaloacetate): Positive RCT ($p = 0.0039$ for fatigue reduction); independent replication needed.

Table I.1: Studies with results expected in 2026–2027, ranked by anticipated impact.

Study	Expected	Why it matters
DecodeME	Mid-late 2026	First adequately powered GWAS ($n > 20,000$); could identify causal genetic loci and enable Mendelian randomisation
BC007 Phase II	2026	Largest RCT ($n = 114$) testing autoantibody-targeted therapy; validates or refutes the functional GPCR autoantibody hypothesis
RECOVER-TLC	End of 2026	First-round results (baricitinib, structured pacing); largest federally funded treatment trials relevant to ME/CFS
BioQuest	2026–2027	Largest ME/CFS biomarker study ($n = 1,000$); could yield first validated blood-based diagnostic panel with disease controls
BioMapAI	2026–2027	Longitudinal multi-omics follow-up; will distinguish state vs trait markers over 4-year disease trajectory
ADDRESS-LC	H1 2026	First CNS-penetrant NF- κ B modulator for Long Covid brain fog; cross-disease (Alzheimer's, Parkinson's) data available
Cornell NAC-GSH	~2026	First dose-response study of NAC on brain glutathione (MRS); could validate oxidative stress as druggable CNS target
NSU Probiotics	~2026	First ME/CFS-specific probiotic RCT with IBS stratification; tests gut–brain axis hypothesis directly
OMF Kynurenine	~2026	First RCT testing kynurenine supplementation; probes tryptophan–serotonin–neuroinflammation axis
Berlin Conference	May 2026	Major venue for unpublished data; BC007, HBOT, and LDN results may be presented
Nacul LDN RCT	Early 2026	First double-blind ME/CFS-specific LDN trial with inflammatory markers and QoL endpoints

- **STOP-PASC / PAX LC** (Paxlovid): Negative results challenge the viral persistence hypothesis; redirects research toward post-infectious immune and metabolic mechanisms.
- **Stellate ganglion block**: Promising pilot ($n = 10$) for autonomic reset; larger sham-controlled RCT likely in planning.
- **HBOT pilot**: Thalamic hyperconnectivity normalised in 30 ME/CFS patients; sham-controlled RCT needed.
- **Cornell cfRNA**: Liquid biopsy classifier (AUC 0.81); multi-site validation with disease controls required.
- **Palomo herpesvirus reactivation**: Multi-virus co-reactivation in 72.5% of patients; anti-dUTPase IgG as potential stratification marker.
- **JAX microbiome AI**: 90% diagnostic accuracy from multimodal gut/blood data; blinded independent replication needed.
- **Post-IM 7-year cohort**: 4% locked-in ME/CFS rate at 24 months; risk factor analysis pending.

I.19 Registry Summary

Table [I.2](#) provides a compact overview of all tracked studies.

Table I.2: Summary of ongoing and planned ME/CFS research studies.

Study	Institution	Status	Cohort	Focus
Rosetta Stone	Imperial College London	Active	$n = 500+$	Multi-omics: ME/CFS vs Long Covid
BioQuest	Uppsala / OMF	Analysis	$n = 1,000$	Multi-omics biomarker panel
DecodeME	Univ. Edinburgh	Analysis	$n > 20,000$	GWAS for ME/CFS
EpiSwitch CFS	Oxford BioDynamics	Validation	$n = 108^*$	Epigenetic diagnostic test
BioMapAI	JAX / Duke	Ongoing	$n = 249$	AI-integrated multi-omics
MEA PhD Project	Rosalind Franklin Inst.	Active	TBD	Metabolites & infection markers
Charité IA	Charité Berlin	Active	TBD	Immunoabsorption (autoantibodies)
BC007 Phase II	Berlin Cures	Analysis	$n = 143$	Autoantibody neutralisation
NCNED TRPM3	Griffith Univ.	Active	TBD	Ion channels + LDN trials
Charité fMRI	Charité Berlin	Funded	TBD	Neuroimaging biomarkers
RECOVER-TLC	NIH multi-site	Active	$n = 600+$	Baricitinib, LDN, GLP-1, pacing
LIFT Trial	Brigham & Women's	Recruiting	TBD	LDN + pyridostigmine
Rapamycin	Multi-site (US)	Active	TBD	mTOR inhibition
Lumbrokinase	Mount Sinai	Recruiting	TBD	Fibrinolytic (microclots)
RESTORE-ME	Terra Biological	Published	$n = 82$	Oxaloacetate (TCA cycle)
Stellate Ganglion	Multi-site (US)	Pilot	$n = 10$	Autonomic reset (SGB)
tVNS	Multi-site	Recruiting	TBD	Vagus nerve stimulation
Masitinib	AB Science	Phase 2	TBD	Mast cell (MCAS)
STOP-PASC/PAX LC	NIH multi-site	Published	TBD	Paxlovid (negative result)
Hydrogen Water	Stony Brook	Recruiting	TBD	Antioxidant dosing
Wearable Study	Scripps Research	Recruiting	TBD	Pacing via wearables
<i>Added March 2026</i>				
MEA-UCL Biomarker	UCL / MEA	Active	Biobank	Blood biomarkers (neuro)
ResetME	Haukeland / Oslo	Recruiting	$n = 66$	Daratumumab (anti-CD38)
UAB LDN	U. Alabama (Younger)	Recruiting	TBD	LDN dose-finding
Cornell NAC-GSH	Weill Cornell	Recruiting	$n = 60$	Brain glutathione (MRS)
NSU Probiotics	Nova Southeastern	Recruiting	$n = 100$	Microbiome / gut-brain axis
ADDRESS-LC	BioVie / DoD	Recruiting	$n = 200$	Neuroinflammation (brain fog)
LC-REVITALIZE	Western Univ. / SILC	Recruiting	$n = 348$	JAK1 + anti-fibrotic
CHIIME	UCSF / PolyBio	Recruiting	TBD	Viral tissue persistence
<i>Added March 2026 (second expansion)</i>				
PrecisionLife	PrecisionLife / DecodeME	Published	$n > 20,000$	Combinatorial genomics (250+ genes)
Cornell RFA 2126 — Chronic Encephalomyelitis	Multi-centre (US)	Published	varied	Energy + immune + vascular
CRM Multi-modal	Multi-centre (US)	Published	varied	Energy + immune + vascular
HBOT Pilot	Multi-site	Published	$n = 30$	Hyperbaric oxygen therapy
Palomo Herpesvirus	Multi-centre	Published	varied	EBV/HHV-6/VZV co-reactivation
Post-IM 7yr	Northwestern	Published	$n = 4,501$	Post-mononucleosis ME/CFS cohort

- [518] D. J. Rossi, C. H. M. Jamieson, and I. L. Weissman. “Haematopoietic ageing in health and lifespan”. In: *Nature Cell Biology* 27 (Jan. 2025). Comprehensive 2025 review demonstrating that aging of HSCs induces systemic inflammation contributing to age-related diseases. Shows that ageing of the haematopoietic system is characterized by phenotypic and functional impairments driven by alterations of HSCs and the bone marrow niche, with emerging insights into its role in driving organismal ageing, particularly in inflammageing and immunosenescence, pp. 195–207. doi: [10.1038/s41556-025-01739-1](https://doi.org/10.1038/s41556-025-01739-1).
- [519] S. J. Morrison and D. T. Scadden. “The aging hematopoietic stem cell niche: a mini review”. In: *Frontiers in Hematology* (2025). Reviews how aging exerts profound impact on the hematopoietic system, leading to increased susceptibility to infections, autoimmune diseases, chronic inflammation, anemia, and hematologic malignancies. Functional decline of HSCs is regarded as a primary driver of age-related hematologic conditions, with the bone marrow microenvironment playing critical regulatory roles. doi: [10.3389/frhem.2025.1525132](https://doi.org/10.3389/frhem.2025.1525132).
- [520] E. M. Pietras, M. R. Warr, and E. Passegué. “Inflammation as a regulator of hematopoietic stem cell function in disease, aging, and clonal selection”. In: *Journal of Experimental Medicine* 218.7 (July 2021). Demonstrates that inflammation is a driving force of HSC aging, causing irreversible exhaustion of functional HSCs. Shows that transient LPS exposure primes aged HSCs to undergo accelerated differentiation at the expense of self-renewal, leading to HSC depletion, with NF- κ B as the central regulator mediating functional impairment. Critical evidence that chronic/repeated immune stimulation depletes HSC reserves, e20201541. doi: [10.1084/jem.20201541](https://doi.org/10.1084/jem.20201541).
- [521] H. Takizawa, S. Boettcher, and M. G. Manz. “Protection of hematopoietic stem cells from stress-induced exhaustion and aging”. In: *Experimental Hematology* 85 (May 2020). Shows that HSCs can be induced to proliferate and differentiate in response to stress signals during infection, inflammation, chemotherapy, radiation, and aging. Critically demonstrates that with chronic or repeated stimulation, HSCs show loss of function and exhaustion. Provides mechanistic framework for understanding how repeated crashes could deplete HSC reserves in ME/CFS, pp. 1–5. doi: [10.1016/j.exphem.2020.04.002](https://doi.org/10.1016/j.exphem.2020.04.002).

"Factors Influencing the Prognosis of Patients with Myalgic Encephalomyelitis/Chronic Fatigue Syndrome". In: *Healthcare* 10.10 (Oct. 2022). Retrospective longitudinal study (n=168, median 55-month follow-up) identifying diagnostic delay as critical prognostic factor. Recovered/improved patients had median 23-month diagnostic delay vs 55 months for non-recovered (p=0.0004). Multivariate analysis: diagnostic delay inversely associated with recovery/improvement (OR 0.98, p=0.036). Older age at onset paradoxically associated with better outcomes (OR 1.06, p=0.028). Recovery rate 8.3%, improvement 4.8%. Demonstrates critical window for intervention and importance of early diagnosis, p. 1958. doi: [10.3390/healthcare10101958](https://doi.org/10.3390/healthcare10101958). Watanabe. “Neuroinflammation in Patients with Chronic Fatigue Syndrome/Myalgic Encephalomyelitis: An ^{11}C -(R)-PK11195 PET Study”. In: *Journal of Nuclear Medicine* 55.6 (2014). Landmark PET neuroimaging study demonstrating elevated translocator protein (TSPO) binding—a marker of microglial activation—in cingulate cortex, hippocampus, amygdala, thalamus, midbrain, and pons of ME/CFS patients vs. healthy controls (45–199% higher BP values). Regional neuroinflammation correlated with cognitive impairment, pain, and depression severity. Provides direct in vivo evidence for the neuroinflammatory substrate that would drive A2A upregulation and adenosine dysregulation in ME/CFS. Study design: n=9 CFS/ME patients, n=10 controls., pp. 945–950. DOI: [10.2967/jnumed.113.131045](https://doi.org/10.2967/jnumed.113.131045). URL: <https://doi.org/10.2967/jnumed.113.131045>.
- [571] M. Navia et al. “Adenosine Receptors as Neuroinflammation Modulators: Role of A1 Agonists and A2A Antagonists”. In: *Cells* 9.7 (2020). Demonstrates that A1 agonists prevent cytokine cocktail (TNF-alpha, IL-1beta, IFN-gamma) induced inflammation in mixed glial cells. A2A antagonism shows superior anti-inflammatory and antioxidant properties in both in vitro and in vivo neuroinflammation models. Authors conclude that A2A antagonism is a candidate therapeutic strategy for chronic neuroinflammation. Provides mechanistic rationale for A2A antagonist-based therapies in conditions with sustained neuroinflammation such as ME/CFS., p. 1739. DOI: [10.3390/cells9071739](https://doi.org/10.3390/cells9071739). URL: <https://doi.org/10.3390/cells9071739>.
- [572] J. V. Rétey, M. Adam, R. Khatami, U. F. O. Luhmann, H. H. Jung, W. Berger, and H.-P. Landolt. “A genetic variation in the adenosine A2A receptor gene (ADORA2A) contributes to individual sensitivity to caffeine effects on sleep”. In: *Clinical Pharmacology & Therapeutics* 81.5 (2007). Pharmacogenetic study demonstrating that the ADORA2A c.1083T>C single nucleotide polymorphism determines individual sensitivity to caffeine-induced sleep disruption. The ADORA2A genotype determines how closely caffeine-induced changes in brain electrical activity during sleep resemble insomnia patterns. Caffeine sensitivity is a functional readout of A2A receptor sensitivity, establishing genetic variation as a modulator of adenosine sleep signaling. Relevant to understanding ME/CFS patients’ variable caffeine responses., pp. 692–698. DOI: [10.1038/sj.clpt.6100102](https://doi.org/10.1038/sj.clpt.6100102). - [573] R. Maksoud, N. Eaton-Fitch, M. Matula, H. Cabanas, D. Staines, and S. Marshall-Gradisnik. “Systematic Review of Sleep Characteristics in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome”. In: *Healthcare* 9.5 (2021). Systematic review of sleep characteristics in ME/CFS. Key finding: increased microarousal index (MAI) is the most consistent polysomnographic abnormality—all five studies measuring MAI found significant increases vs. healthy controls, indicating pathological sleep fragmentation.

Major discrepancy between subjective sleep complaints (91% of patients) and objective polysomnographic measures. Sleep onset latency is consistently normal, suggesting the primary pathology is in sleep maintenance and quality, not initiation. The fragmentation pattern is consistent with an adenosine-mediated sleep pressure abnormality causing intermittent arousal., p. 568. DOI: [10.3390/healthcare9050568](https://doi.org/10.3390/healthcare9050568). URL: <https://doi.org/10.3390/healthcare9050568>.

In: *European Journal of Neurology* 13.1 (2006). n=29 CFS patients with DLMO later than 21:30h. Open-label: 5mg melatonin orally 5h before DLMO for 3 months. CIS questionnaire: total score and sub-scores for fatigue, concentration, motivation, and activity improved significantly. Fatigue normalised in 8/27 vs. 2/29 pre-treatment (significant). Patients with DLMO later than 22:00h (n=21) showed greater benefit than

- earlier DLMO group (n=8). Supports DLMO-guided melatonin timing; no control group limits causal inference., pp. 55–60. doi: [10.1111/j.1468-1331.2006.01132.x](https://doi.org/10.1111/j.1468-1331.2006.01132.x).
- [586] A. Z. Mohamed, T. Andersen, S. Radovic, P. Del Fante, R. Kwiitek, V. Calhoun, S. Bhuta, D. F. Hermens, J. Lagopoulos, and Z. Y. Shan. “Objective sleep measures in chronic fatigue syndrome patients: A systematic review and meta-analysis”. In: *Sleep Medicine Reviews* 69 (2023). Systematic review and meta-analysis: 24 case-control studies; 20 adult studies (ME/CFS n=426, controls n=375) and 4 adolescent studies (ME/CFS n=242, controls n=235). Adults: longer sleep onset latency, longer WASO, reduced sleep efficiency, decreased stage N2, more stage N3 (SWS), longer REM latency. Adolescents: longer TIB, longer TST, longer SOL, reduced efficiency. Results suggest autonomic (sympathetic/parasympathetic) alterations in ME/CFS. No conflicts of interest., p. 101771. doi: [10.1016/j.smr.v.2023.101771](https://doi.org/10.1016/j.smr.v.2023.101771).
- [587] C. Liang, R. Song, J. Zhang, J. Yao, Z. Guan, and X. Zeng. “Melatonin enhances NK cell function in aged mice by increasing T-bet expression via the JAK3-STAT5 signaling pathway”. In: *Immunity & Ageing* 21.1 (2024). Mouse model (aged mice). Melatonin significantly increased NK cell number and function: proliferation, degranulation, and IFN-gamma secretion. Mechanism: JAK3/STAT5 signalling leads to increased T-bet expression, driving NK cell maturation and activation. Relevant to ME/CFS context of NK cell hypofunctionality: melatonin deficit from circadian disruption may contribute to reduced NK cytotoxicity. Erratum published 2024 Oct (minor correction). No conflicts of interest., p. 59. doi: [10.1186/s12979-024-00459-8](https://doi.org/10.1186/s12979-024-00459-8).
- [588] G. Anderson and M. Maes. “Mitochondria and immunity in chronic fatigue syndrome”. In: *Progress in Neuropsychopharmacology and Biological Psychiatry* 103 (2020). Review. Proposes gut and immune cell mitochondria as two central hubs in ME/CFS pathophysiology, interacting with circadian rhythm and melatonin. Also implicates gut microbiome and permeability, endogenous opioidergic system, autonomic nervous system, microRNA-155, viral reactivation, and leptin. Positions melatonin/circadian disruption as upstream regulator of mitochondrial and immune dysfunction in ME/CFS, with therapeutic implications., p. 109976. doi: [10.1016/j.pnpbp.2020.109976](https://doi.org/10.1016/j.pnpbp.2020.109976).
- [589] H. J. Burgess, V. L. Revell, T. A. Molina, and C. I. Eastman. “Human phase response curves to three days of daily melatonin: 0.5 mg versus 3.0 mg”. In: *Journal of Clinical Endocrinology & Metabolism* 95.7 (2010). n=34 healthy adults (16M/18F, ages 18–42), double-blind placebo-controlled. Phase response curves for 0.5mg vs 3.0mg oral melatonin. Maximum circadian phase advances with 0.5mg occurred 2–4h before DLMO or 9–11h before sleep midpoint. When each dose given at its optimal time, both 0.5mg and 3.0mg produce similarly sized phase advances and delays. Optimal timing for advances is later for the lower dose. Supports low-dose (0.5mg) melatonin as effective chronobiotic without suppressing endogenous secretion., pp. 3325–3331. doi: [10.1210/jc.2009-2590](https://doi.org/10.1210/jc.2009-2590).

First hypothesis paper proposing impaired glymphatic function as a contributor to ME/CFS pathophysiology. Argues that the unrefreshing sleep and cognitive impairment in ME/CFS may reflect failure to adequately clear brain metabolic waste during sleep. Proposes CSF diversion (lumboperitoneal shunting) as a testable but invasive intervention for severely affected patients. Foundational paper for glymphatic-ME/CFS hypothesis., pp. 142–145. doi: [10.1016/j.mehy.2018.07.007](https://doi.org/10.1016/j.mehy.2018.07.007).
- [606] C. J. Woolf. "Central Sensitization: Implications for the Diagnosis and Treatment of Pain". In: *Pain* 152.3 Suppl (2011). Landmark Harvard review by Woolf defining central sensitization: nociceptor-driven increase in excitability of central nociceptive neurons. Key mechanisms: wind-up (temporal summation), LTP-like synaptic plasticity in dorsal horn, NMDA receptor activation. Demonstrates central sensitization in fibromyalgia, musculoskeletal disorders, visceral pain syndromes. Comorbidity pattern suggests shared central mechanism. Foundational reference for nociplastic pain framework., S2–S15. doi: [10.1016/j.pain.2010.09.030](https://doi.org/10.1016/j.pain.2010.09.030).
- [607] E. Kosek. "The Concept of Nociplastic Pain—Where to from Here?" In: *Pain* 165.11S (2024). 2024 IASP perspective by Kosek on nociplastic pain (third mechanistic descriptor, adopted 2017). Defined as pain from altered nociception not fully explained by nociceptive or neuropathic mechanisms. Clinical criteria for musculoskeletal nociplastic pain: >3 months duration, regional/widespread distribution, not explained by other mechanisms, clinical signs of hypersensitivity. Fibromyalgia as prototype. Peripheral sensitization (autoreactive antibodies at DRG) and central mechanisms (aberrant brain network architecture) may both contribute. Advocates opioid avoidance; pharmacological approaches resemble neuropathic pain treatment., S50–S57. doi: [10.1097/j.pain.0000000000003305](https://doi.org/10.1097/j.pain.0000000000003305).
- [608] M. L. Pall. "Common Etiology of Posttraumatic Stress Disorder, Fibromyalgia, Chronic Fatigue Syndrome and Multiple Chemical Sensitivity via Elevated Nitric Oxide/Peroxynitrite". In: *Medical Hypotheses* 57.2 (2001). Extension of Pall 2000 hypothesis proposing NO/ONOO- vicious cycle as common etiology for CFS, FM, MCS and PTSD. Evidence: shared symptoms, frequent comorbidity, common short-term stressor induction, similar biochemical findings. Six positive feedback loops proposed to sustain elevated peroxynitrite. Mechanism: iNOS induction by stressors -> NO + superoxide -> peroxynitrite -> NF-kB activation -> more iNOS. Medical Hypotheses – low certainty, not empirically tested in RCTs., pp. 139–145. doi: [10.1054/mehy.2001.1325](https://doi.org/10.1054/mehy.2001.1325).

Conference presentation IACFS/ME 2016 page 35. Pilot open-label 1800 mg/day NAC × 4 weeks. First proof NAC crosses BBB and elevates cortical GSH in vivo. Symptom improvements: $p=0.006$. Led to NIH RCT NCT04542161 (completion April 2026). NOT YET PEER-REVIEWED PUBLICATION. 2016.
- [610] K. Yang, J. Xu, M. Fan, F. Tu, X. Wang, T. Ha, D. L. Williams, and C. Li. “Lactate Suppresses Macrophage Pro-Inflammatory Response to LPS Stimulation by Inhibition of YAP and NF- κ B Activation via GPR81-Mediated Signaling”. In: *Frontiers in Immunology* 11 (2020). Mechanistic study in Raw 264.7 and bone marrow-derived macrophages. Lactate via GPR81 activates AMPK and LATS to phosphorylate and inactivate YAP transcriptional co-activator; YAP inactivation disrupts YAP-NF- κ B p65 interaction, reducing TNF- α and IL-6 production. GPR81 (HCA1/HCAR1) is the lactate receptor. Provides mechanistic basis for the anti-inflammatory paradox of lactate at high exercise loads in ME/CFS: the GPR81 brake may be desensitized or dysfunctional. Foundational for section 15.13 metabolic danger signals., p. 587913. doi: [10.3389/fimmu.2020.587913](https://doi.org/10.3389/fimmu.2020.587913).
- [611] M. Vink. “The Aerobic Energy Production and the Lactic Acid Excretion are both Impeded in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome”. In: *Journal of Neurology and Neurobiology* 1.1 (2015). Case study of severe ME/CFS patient (former Dutch National Field Hockey Champion) showing 6-fold delay in lactate excretion after trivial exercise (6-yard walk to bathroom), with lactate levels exceeding those of professional athletes. Demonstrates both impaired aerobic energy production and severely delayed lactate clearance in severe ME/CFS. doi: [10.16966/2379-7150.112](https://doi.org/10.16966/2379-7150.112). - [614] X. Yang, D. Lee, H. W. Kim, B.-H. Park, C. Lim, and E. J. Bae. “Cannabidiol Inhibits IgE-Mediated Mast Cell Degranulation and Anaphylaxis in Mice”. In: *Molecular Nutrition and Food Research* 68.3 (2024). Mechanistic study in mouse/human primary mast cells. CBD suppresses antigen-stimulated mast cell degranulation concentration-dependently by inhibiting Fc ϵ RI downstream signaling and calcium mobilization. Importantly, suppressive effects are CB1- and CB2-independent (preserved in receptor-depleted cells), suggesting novel non-canonical mechanisms. CBD also inhibits mast cell development in long-term culture. In vivo: CBD suppresses passive cutaneous anaphylaxis. Highly relevant to MCAS-subset ME/CFS with mast cell brake failure., e2300136. doi: [10.1002/mnfr.202300136](https://doi.org/10.1002/mnfr.202300136).
- [615] E. B. Russo. “Clinical Endocannabinoid Deficiency (CECD): Can This Concept Explain Therapeutic Benefits of Cannabis in Migraine, Fibromyalgia, Irritable Bowel Syndrome and Other Treatment-Resistant Conditions?” In: *Neuro Endocrinology Letters* 25.1-2 (2004). Original CECD hypothesis paper by Russo. Proposes that deficient en-

- docannabinoid tone (low anandamide/2-AG, impaired CB receptor signaling) underlies fibromyalgia, migraine, IBS and related conditions. Evidence: cannabinoids block spinal, peripheral and GI pain mechanisms; anandamide active in periaqueductal gray (migraine generator); THC modulates NMDA receptors. Fibromyalgia conceptualized as central sensitization state. Suggests CSF examination and neuroimaging for objective CECD testing. Medical Hypotheses quality; later supported by CSF anandamide data in migraineurs., pp. 31–39.
- [616] E. B. Russo. “Clinical Endocannabinoid Deficiency Reconsidered: Current Research Supports the Theory in Migraine, Fibromyalgia, Irritable Bowel, and Other Treatment-Resistant Syndromes”. In: *Cannabis and Cannabinoid Research* 1.1 (2016). Updated CECD review 12 years after original paper. New evidence: statistically significant CSF anandamide reductions in migraineurs; advanced imaging showing ECS hypofunction in PTSD. Central sensitization/hyperalgesia common to migraine, FM, IBS – consistent with ECS hypofunction. Additional evidence for decreased pain, improved sleep with cannabinoid treatment. Discusses adjunctive lifestyle approaches affecting ECS tone (exercise, sleep, stress reduction). Open access. Peer-reviewed., pp. 154–165. doi: [10.1089/can.2016.0009](https://doi.org/10.1089/can.2016.0009).
- [617] K. Friston. “The Free-Energy Principle: A Unified Brain Theory?” In: *Nature Reviews Neuroscience* 11.2 (2010). Landmark review by Friston proposing free energy minimization as a unified principle for perception, action and learning. Key concept: brain as a generative model minimizing surprise (free energy/prediction error). Perception = updating beliefs to match sensory data; action = changing sensory data to match beliefs. Underpins active inference and predictive coding frameworks. Foundational theory for interoceptive prediction error model of ME/CFS symptoms. *Nature Reviews Neuroscience*, high impact., pp. 127–138. doi: [10.1038/nrn2787](https://doi.org/10.1038/nrn2787).
- [618] Y. Kadota, G. Cooper, A. R. Burton, J. Lemon, U. Schall, A. Lloyd, and U. Vollmer-Conna. “Autonomic Hyper-Vigilance in Post-Infective Fatigue Syndrome”. In: *Biological Psychology* 85.1 (2010). Case-control study (23 post-infective fatigue syndrome, 25 healthy controls). PIFS associated with: higher heartbeat discrimination accuracy (heightened interoceptive sensitivity), lower pressure pain threshold, insensitivity to Stroop task difficulty in cardiac response, lack of cardiac habituation. Heightened interoceptive sensitivity strongly correlated with current symptoms. First evidence of autonomic hyper-vigilance in post-infective fatigue – consistent with attentional bias toward internal body signals predicted by interoceptive inference model. Directly supports section 15.15., pp. 97–103. doi: [10.1016/j.biopsycho.2010.05.009](https://doi.org/10.1016/j.biopsycho.2010.05.009).

Takishima. “Decreased nitric oxide-mediated natural killer cell activation in chronic fatigue syndrome”. In: *European Journal of Clinical Investigation* 28.11 (1998). In vitro study (n=20 CFS, n=21 controls) demonstrated that L-arginine treatment (24h) significantly enhanced NK cell activity in healthy controls but failed to produce any effect in CFS patients. Even direct NO donor compounds did not activate NK cells in patients. While iNOS gene expression was normal in both groups, the functional NO-mediated immune activation pathway was impaired. Indicates that L-arginine supplementation alone may be insufficient; suggests need for combination therapy addressing downstream pathway dysfunction (e.g., BH4 cofactor)., pp. 937–943. doi: [10.1046/j.1365-2362.1998.00373.x](https://doi.org/10.1046/j.1365-2362.1998.00373.x).
- [836] S. Myhill, N. E. Booth, and J. McLaren-Howard. “Targeting mitochondrial dysfunction in the treatment of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) – a clinical audit”. In: *International Journal of Clinical and Experimental Medicine* 6.1 (2012). Clinical audit of comprehensive mitochondrial support protocol in 138 ME/CFS patients. All 30 compliant patients (with follow-up testing) showed improvements in mitochondrial function: average 4.14x increase in Mitochondrial Energy Score, 100% improved in oxidative phosphorylation, 93% improved in ATP availability. Protocol included stone-age diet, sleep optimization, comprehensive supplementation (L-carnitine, glutathione, CoQ10, niacinamide, B12, D-ribose, magnesium), and pacing. Four non-compliant patients showed minimal improvement, demonstrating requirement for sustained adherence. Limitation: not RCT, specific dosages not provided., pp. 1–15.
